1 Introduction to Authoring in LON-CAPA

LON-CAPA is a web-based content management system that helps to organize and present your course website, deliver and manage assignments, and manage student enrollment, assessment, and grading. Typically all author functions will be completed using a web browser (Firefox, Chrome, Safari, IE or similar). The one exception to this is where your LON-CAPA domain has been configured to support webDAV access, in which case you may be able to carry out standard file operations (copy, move, add file etc.) using your computer's standard filesystem interface, after you have established access to your authoring space volume.

LON-CAPA has three work spaces: the ROLES menu, the course/community space where courses are developed from resources, and the authoring space where resources are composed and published. There are two user manuals for LON-CAPA, a course coordinator manual and author manual. Also, there are quick reference guides to building a course and building an exam, available at http://help.loncapa.org. This is the author manual used to create resources such as problems that can later be added to your course.

Before creating problems, you should have:

- developed learning objectives that you want to evaluate for your course/community
- determined the appropriate question formats and developed your problems for input into LON-CAPA. Examples for question formats are provided in this manual and also when authoring a problem.
- developed the directory structure that you plan to use to organize your resources

Overview of the Authoring Process

Graphics, problems, and html pages are all considered **resources**. Additional resources include reusable snippets of perl, xml, cascading style sheets, etc. This manual documents the process used to create and organize the more advanced types of resources.

The authoring process involves these steps:

- create or upload a resource. The resource can combine other uploaded resources such as graphics, code snippets, or problem sequences
- test and revise your resource
- publish the resource to make it available for integration into a course/community and/or sharing
- revise your resources after publishing to improve clarity or eliminate bugs

Importance of Planning your Directory Structure

Once a resource has been published, the published version can never be moved or deleted. Thus, it is important to plan your folder structure. Old resources can be marked obsolete, and the version in your authoring space deleted, but the published version(s) will remain in your folders in the locations in which they were originally published.

Understanding xml and the Colorful Editor

Problems are written in xml markup, which can appear complex when you first start to work with LON-CAPA if you have not done html or other coding. However, each xml element has a starting and closing argument, just like html. This manual includes a reference on xml markup used to write problems.

The authoring environment includes a 'colorful' web-based editor that can be used for authoring your first problems. Even experts will often start with the colorful editor to build a template for a problem. It is possible to switch back and forth between the colorful editor and xml when composing and testing your problems. Often simple issues are easier to clean up directly in xml. Also, it is easier to copy/paste xml to build additional problem sections compared to using the colorful editor.

Scripts

The power of LON-CAPA for problem randomization and computing randomized answers is realized through writing perl script at the top of a problem. Example scripts are included in many example problems, and most resource authors publish scripts with the problems, so many examples are available. Many special functions have been created for use in scripts. This manual includes a section on writing scripts.

Maxima and R

Two computer algebra systems are interfaced to LON-CAPA, Maxima and R. This provides for algebra and calculus problems and responses. The R system has strong capabilities for statistics. Special script functions are provided to call Maxima and R to generate correct responses for a randomized problem, and also to check student responses.

Comments

Commenting your xml and scripts is important for both you and other users. Commenting within a loncapa/perl script is denoted with a #. This can be entered anwhere in a line and the remainder of the line will be ignored when parsing. Problems are coded in xml. Comments in xml are of the format <!-- comment -->. However, it is important to know that the XML comments propagate through to the rendered web page viewed by students while the perl comments within the script are not. Hence, writing solution hints within XML comments is discouraged for obvious reasons.

1.1 About This Manual

Throughout this manual, keywords and phrases literally present on the computer screen will be referred to in **bold type**. Function names and scripts will be shown in a **typewriter** font.

1.2 Login as Content Author

To begin using LON-CAPA, you first need to log in to your account on LON-CAPA. Open your web browser and navigate to your local LON-CAPA URL. You will be presented with a log in screen.

Fill in the Username and Password boxes with your information. Then press the Login button. This will take you to your LON-CAPA User Roles menu.

Figure 1: LON-CAPA Log in screen

Note: Your Username and Password will be given to you by your system administrator. Both are case sensitive, so make sure you type them with the correct case.

1.3 Roles Screen

After logging into LON-CAPA with your username and password, you will see a screen where you can select your ROLE. LON-CAPA is a roles-based system. You can always use the same login even though your roles may change. You can be an instructor in one class, a TA for another class, and an author of resources – all with the same username. Selecting **Roles** at the top right of a page, or **Switch to another user role** on the Main Menu page will bring you back to the **Roles** screen.

Two main types of Roles exist in LON-CAPA: Authoring Roles, and Course Roles. Authoring roles are used to develop learning resources. The course role is where resources are inserted into courses. You may have multiple instances of either type of role. For example, each separate course has a course role. You may make use of more than one authoring space role depending on your involvement in collaborative LON-CAPA content creation.

1.4 Menu Options

1.4.1 Inline Menu

Author Inline Menu

The default menu system is the Inline Menu. Links are available near the top of screens.

Figure 2: Author Remote Control

1.4.2 Remote Control

Remote Control

LON-CAPA also offers a *Remote Control* menu. The Remote Control is a separate popup browser window, and is automatically sized and placed in the upper left of the screen. To enable and experiment with the Remote Control menu, navigate to: Main Menu > My Space > Set my user preferences > Content Display Settings > Launch Remote Control. To exit from the remote, either close the window, or look for the inline menu command to exit on the upper right of the parent browser window.

Hints for each button appear when hovering over the buttons. Click the words *Extended Display* immediately above the remote command display to obtain a list of hints.

The commands available on the remote change depending on whether you are in a authoring role or course role, and, in the case of a course role, change depending on the functionality available to your current role for the screen currently displayed in the main browser window. Some of the important commands on the Remote Control are:

- **ROLES (CHOOSE ROLE)** opens the roles screen for you to select which user role to assume.
- CCAT (COURSE CATALOG) opens search for courses/communities.
- CUSR (CHANGE USER PRIV) add/manage user privileges.
- AUTH (AUTHORING SPACE) displays the authoring space for your account.
- **RES (RESOURCE SPACE)** allows you to browse the LON-CAPA network directory. (Searching resource space is usually preferred unless you know where to look for a particular resource.)
- COM (COMMUNICATION) allows you to access the communication functions in the system.

- **SRCH (SEARCH LIBRARY)** brings up a screen that lets you search the LON-CAPA resources using multiple criteria.
- **PREF (PREFERENCES)** brings up a screen that allows you to change some preferences.
- EXIT (LOGOUT) will log you out of the LON-CAPA system.

1.5 Resource Types

LON-CAPA provides several types of resources for organizing your course website. Resource behavior is determined by file extension. Valid extensions are: .xml, .html, .ktml, .htm, .xhtm, .problem, .page, .sequence, .rights, .sty, .task, .library, .js, .css, .txt.

• A .css cascading style sheet file can be published for use in multiple courses. Use of a specific CSS style within a resource can be set using an html tag within a text block that refers to a class by name, where the class is included in the published css file. You would specify use of the css file with a link> tag, and indicate a file dependency with an allow tag (if the <allow> tag is not specified LON-CAPA should add it at the first publication step).

```
<startouttext />
<link rel="stylesheet" index="11"
href="/res/yourdomain/yourusername/yourpath/testcss.css" type="text/css" />
<span class="Yellow">After the Earth and Mars, which other body in our
solar system is thought to be the next most likely site for finding
life?</span><endouttext />
<allow src="/res/yourdomain/yourusername/yourpath/testcss.css" />
where testcss.css contains:
.Yellow {
    color: yellow;
}
```

It also possible to indicate use of a css file within a course, course-wide, for a specific folder, or specific resource etc, by setting the parameter: CSS file to link [Part: 0] (cssfile).

• A .html HTML file, (formerly known as a Content Page), displays course content. It is a conventional HTML page. These resources use the extension ".html". By using the "New File.." dropdown, you can enter a file name with one of the other extensions, htm, xhtml, xhtm, xml. For more information see the section 3.

Although the extensions: xhtml and xhtm imply that the file should be xhtml compliant (i.e., be a valid document, according to w3c validation meaning (amongst other things):

all elements closed; attributes case-sensitive; attributes required by certain elements, certain specials characters need to be included as entities in some attributes etc.), LON-CAPA does not test whether a document with an xhtml extension is actually valid xhtml.

Files of type .xml are supported for legacy files, but it is suggested that new files are one of the html varieties. See also the .library file description for xml.

- A .problem Problem resource represents problems for the students to solve, with answers stored in the system. These resources are stored in files that must use the extension ".problem". Problems are coded in a combination of Perl and xml markup tags. Most of this manual concerns authoring problems. For an overview see the section 4.1
- A .page Page is a type of Map which is used to join other resources together into one HTML page. For example, a page of problems will appears as a problem set. These resources are stored in files that must use the extension ".page".

For performance purposes it is best not to include too may resources in a .page (8 would be a good limit; and likely fewer if maxima or R are required for computation). The Course Editor offers a similar tool called a "Composite page" which resides within a course rather than in the published repository.

The underlying XML structure, and behavior of a .page file are the same as used for a "Composite page", which can be added to a course using the Course Editor. One difference between the two is that for a .page in Authoring Space, one of the Authoring Space editors (Simple Edit or Advanced Edit) will be used to modify the contents of the file, whereas for a Composite Page, the Course Editor is used.

Options for reuse of a course Composite page are: (a) use cloning to copy everything from the old course to the new; (b) as course coordinator, copy the Composite map into the Course Editor's clipboard, change role to course coordinator in a different course, and past the item into the other course from the Course Editor's clipboard.

The course manual describes ways to combine resources in folders, which is an alternative to creating composite pages. A potential advantage of a a composite page is that the browser's inbuilt capabilities can be used to print all resources included within a page with a single "Print" call. That said, LON-CAPA's own print utility which creates PDFs allows students to print all resources in a folder to a single PDF, which lessens the advantange that accrues from use of a composite page. The disadvantage of use of a published .page is that once a .page is published, reordering or modifying the contents requires use of the resource assembly tool in authoring space, followed by republication. Publishing a .page in the repository is suggested if the content does not need to change.

For more information on .pages, see the section 14.5

• A .js javascript file contains javascript code which might be referenced with HTML in a textblock in a LON-CAPA problem in a manner similar to a .css file.

- A .library library file contains LON-CAPA XML which can be imported into other .problem files. Typically a .library file will hold commonly used subroutines, or data structures (to be called in LON-CAPA perl script blocks). It is included in a problem in the colorful editor by using the "Import a File" selection in a dropdown list in the colorful editor.
- A .sequence sequence is a type of Map which is used to link other resources together. The users of this resource can use links to follow the sequence. Sequences are stored in files that must use the extension ".sequence". Sequences can contain other sequences and pages.

A published sequence contains XML which describes which LON-CAPA resources are to be grouped together in a folder. If a .sequence file is imported in its entirety then there is limited control over which specific resources are shown, and in which order. The "Randomorder" and "Randompick" checkboxes in the Course Editor can be used to cause the resources to be displayed in a randomorder (randomized for each user), and to display M of the total N resources in the sequence (again the choice of which M are shown is randomized for each user). By contrast, if the "Import from Assembled Map", a "Select Map" link will allow all resources in the published sequence to be imported into the current folder, as distinct resources, allowing them to be reordered, and cut/removed, as preferred using the standard Course Editor tools.

Conditional sequences are published sequence files for which conditions have been specified for one or more links between resources in the map. These have to be created using the "Advanced Edit" button when creating a new sequence file in Authoring Space. These are the types of sequence for which a student's progress through a series of resources can be specified. Grading of conditional sequences can be complicated.

- A .rights file is used to specify custom access rights for a published resource. The access rights to apply to a specific resource are specified on publication (or republication) of the resource. A .rights file also must be published to be selectable during resource publication as a "Custom Distribution File" when "Customized right of use ..." is selected from the "Copyright/Distribution" dropdown list. See the "Publishing A Resource" section 12.2.
- A .sty is a LON-CAPA style file used to apply custom styling to specific tags in a LON-CAPA problem. The styles defined in the file can be applied to display of all resources in a course using:

Main Menu->Modify course configuration->Display of resources (checked) + click "Display" button->Click "Select Style File" link (Default XML style file item) to launch window to select published .sty file, then click "Save Changes" in main window.

Style files can contain different instructions for different targets (e.g., web or tex). For example, the following style file would replace the <h1>-tag in all incorporated pages by the annoying <blink>-tag:

<definetag name = "h1">

```
<meta></meta>
<render>
<web><blink></web>
<tex>\section{</tex>
<latexsource>\section{</latexsource>
</render>
</definetag name = "/h1">
<meta></meta>
<render>
<web></blink></web>
<tex>}</tex>
```

```
<latexsource>}</latexsource>
</render>
</definetag>
```

When printing, LON-CAPA will use the tex \section as <h1>-rendering.

Note that .css is perhaps a more modern way to achieve formatting.

• A .task task file is a bridge task file. Bridge tasks permit assessment using rubrics. See the Bridge Task section 17.

1.6 Description of Authoring Space

The Authoring Space is the environment in LON-CAPA where you create and update your course resources. Creating content involves both *authoring* the resource during editing, and then *publishing* the resource to make it available for use in courses. The figure 3 shows the top menu. If you move your mouse pointer over your name at the top left of the page, a dropdown box will be displayed which you can use to select "Preferences" (see Setting Preferences in the course coordination manual).

The displayed menu also includes:

- Main Menu provide links to additional personal settings.
- Authoring Space returns you to the current authoring space.
- Browse provides a link to published resources.
- **People** provides a menu to add coauthors.

The gray bar under the menu provides a clickable bread crumb trail. The current **authoring space** folder location is displayed near the bottom of the figure 3, and is clickable. The **Recent** dropdown box lists recent folder locations for quick navigation.

The upper right menu is not shown here, but includes the following links:

Your Name * (A	uthor)		
Main Menu	Authoring Space	Browse	People
Authoring Spa	ice		
Authoring Sp	ace:/priv/msu/ <use< td=""><td>rname>/<cu< td=""><td>rrent directory></td></cu<></td></use<>	rname>/ <cu< td=""><td>rrent directory></td></cu<>	rrent directory>
- Recent		-	-

0	Select action 🛟	<u>my_file.html</u> (<u>Edit</u>) (<u>Clean Up</u>)	<u>Edit Metadata</u>	Unpublished	Tue Jun 25 03:36:17 pm 2013 (EDT)

Figure 4: Example of Author Directory

- Message links to your e-mail box.
- Roles returns you to your roles page.
- **Help** provides a link to online help for the authoring space. The online help is a modified version of this manual.
- Logout is a link to close the session.

At the bottom of the page is a directory as shown in the figure 4. On the left edge, icons help identify the content type. The **Actions** dropdown provides commands to move, copy, paste, publish the resource or other content-type-dependent options. The **Name** column provides a link to the resource or folder. The **Title** column provides a link to the meta data provided to help other users find your resource. The **Status** column shows whether the resource is **Published**, **Unpublished**, or **Obsolete**. The vertical bar (pink in the figure) color denotes the status: Green (published); Pink (unpublished); Gray (obsolete).

In the center of the page are three action menus: Actions for current directory, Upload a new document, Create a new directory or LON-CAPA document. The first two menus are intuitive when exploring them. The third menu is shown in the figure 5 and new content types are described later in this manual.

Select Action New file: New HTML file:	Type Name Here	Go
New problem:		
New assembled page. New assembled sequence: New custom rights file: New style file: New bridgetask file: New library file:		

Figure 5: New Content Menu

1.7 Searching Existing Resources

The Basic search page allows you to specify a phrase or expression to search for in the LON-CAPA resource repository. Search strings can contain quoted phrases, multiple words, '-' (meaning "not"), and multiple words or phrases joined with 'or'. For example:

- **cat** Matches resources about cats.
- cat or dog Matches resources about cats or dogs.
- cat dog Matches resources about both "cat" and "dog".
- "fluffy cat" -dog Matches resources on the phrase "fluffy cat" that do not contain "dog".

There are two checkboxes on the basic search page. The first allows you to limit your search to the domain of the machine you are currently logged into. The second causes a thesaurus lookup of your search phrase. Search results will include resources which match any of the related phrases as well as the original phrase.

The resource metadata fields searched in a basic search are listed below. It is worth noting that the data searched are self-reported by the resource author. In many cases, authors are unable to provide relevant values for the fields searched. If you need to search based on properties other than the following, use the 1.7 Advanced Search link on the basic search page.

- title
- author
- subject
- notes

- abstract
- keywords

The Advanced Search in LON-CAPA allows you to search specific metadata fields for matching resources. Resources which match all of the constraints specified will be returned.

For many of the search fields, a "related words" checkbox is available. This causes each search term or quoted phrase in the search for that field to be matched in our thesaurus. Resources which matches in the given field any of the search phrases (depending on the logic in the original search phrase) will be returned.

The following fields can be searched:

- Title
- Author
- Publisher/Owner
- Author Space
- Last Modifying User
- Keywords
- Notes
- Abstract
- Standards
- Mime type
- Lowest grade level
- Highest grade level
- Domain
- Copyright
- Language
- Creation and Modification Dates

Dynamic metadata, computed based on resource usage statistics, can be searched as well. The following fields can be searched, with a minimum or maximum value being specified:

- Network-wide number of accesses (hits)
- Total number of students who have worked on this problem

- Average number of tries till solved
- Degree of difficulty
- Degree of discrimination

Evaluation data may be searched, with a minimum or maximum value being specified:

- Material presented in clear way
- Material covered with sufficient depth
- Material is helpful
- Material appears to be correct
- Resource is technically correct

1.8 Browsing Existing Resources

Click Browse published resources on the Main Menu to browse the LON-CAPA resource pool. This is the same interface used when importing a document into your course documents except that you only have permissions to view the resources, not select them for importing. Note that at the top of the Resource Space Screen there are some options. For example, selecting "Title" will display the titles from the metadata from each problem. Selecting "All versions" will show all versions of the resource which are saved whenever the resource was republished.

The resources are organized by the domain, then the username. The **Recent** dropdown box provides a shortcut to recent browsing history.

2 Help

2.1 Online Help

On many LON-CAPA pages, you will see one or more small blue circles (each with a white question mark inside) **(2)**. These blue circles are links to relevant help documentation. Each LON-CAPA help page also includes a search box, in which you can enter keyword(s) to search all LON-CAPA help documents.

Also, a **Help** link is available in the upper right. This help page provides links to the course manual (from within a course) or the author manual (from the authoring space) and provides both an online version and pdf version. You may wish to save a pdf version of each so that you can reference the help for one role while working in the other role. The help page also provides a link to request help from the LON-CAPA help desk and a link to report bugs (Course Coordinators and Authors only). In some cases you may also see a green square containing a white question mark alongside the text: "FAQ". This provides a link to relevant help item in the user-contributed documentation found in the LON-CAPA FAQ-o-matic system.

2.2 Where to Find Additional Help

You can find additional help about LON-CAPA and download copies of this manual at http://help.lon-capa.org. For additional help, use the Help link on the upper right of the screen to find a link to contact the helpdesk, or search the loncapa listservs at http://mail.lon-capa.org/mailman/swish.cgi. You may wish to join the listserv loncapa-users at http://mail.lon-capa.org. The family of users is very helpful in assisting users with questions posted to the listserv.

2.3 Requesting New Features and Submitting Suggestions

We Welcome Your Ideas and Contributions...

LON-CAPA is open-source software where everyone is free to contribute to the development. If you think of an enhancement, or find a bug in the system, please report it. LON-CAPA uses Bugzilla (http://www.bugzilla.org/) to report and track bugs and enhancement requests. All reported bugs and enhancement requests posted on Bugzilla are examined by the core LON-CAPA team. Having the request in Bugzilla helps keep track of both bugs and feature requests, and is the preferred method of reporting bugs and requesting enhancements. You'll be able to see how the developers respond to the bug, which developer is currently responsible for it, and what the developer's intentions are.

You must have an account to use Bugzilla. You can create an account at http://bugs.lon-capa.org by clicking on the link Open a New Bugzilla Account. You will be directed to send an e-mail to the LON-CAPA Helpdesk to request creation of a Bugzilla account. Once you have an open account, please search existing cases for related content before submitting a new case. Select "LON-CAPA" in the "Product" category when searching. Hold the Ctrl key while clicking multiple items. The "Component", "Version", and "Target" can be left undesignated. If you find a related bug, you can add comments instead of reporting a new bug. If you find a bug that you are interested in following, you

You can report a bug or request an enhancement as follows:

can add your e-mail to the "Add cc:" box and click "Commit".

- 1. Open the web page http://bugs.lon-capa.org
- 2. Click on the Enter a new bug report link.
- 3. Select the (LON-CAPA) product link.
- 4. At the login screen, enter your e-mail address and password.
- 5. Click the [Login] button.
- 6. Select the LON-CAPA Version, Component, Platform and Operating System (as much as known).
- 7. Enter a summary in the "Summary" text box.
- 8. Enter a description in the "Description" text box.

- 9. Click the [Commit] button.
- A developer will follow up with you.

3 HTML Page Overview

HTML files are HTML documents that display the course information you are presenting. They have been previously called Content Pages.

You may create HTML files and then upload them, or you may create HTML files within the Authoring Space.

4 Problem Types in LON-CAPA

4.1 Problem Types

In this manual we will cover basic types of problems: Radio Response, Option Response, String Response, Numerical Response, Formula Response, and Math Response. You will need to identify which types of problem you want to use and create appropriate questions for your course.

4.1.1 Foils

In the LON-CAPA system, a **Foil** is the statement next to the drop-down box or radio button in a Radio Response or Option Response problem. Foils do not need to be text; they can be images or other resources.

4.2 Radio Response Problems

Radio Response problems present a list of foils with radio buttons. The student can select *one* of these statements by clicking the appropriate radio button.

4.3 Option Response Problems

Option Response problems present foils to the student with drop-down boxes. The student can select the matching choice for the foils from a list of choices. Optionally, the foils may be bundled into Concept Groups and the system will select one foil from each group to display to the student.

By default, the list of options is presented in front of the foils. Using the optional <drawoptionlist /> tag, the list of options can be embedded into the foil.

4.3.1 Option Response Problems with Concept Groups

Each **Option Response** problem can have three parts:

1. The Concept Groups

Figure 6: Option Response Problem

- 2. The options for the students to select, by default "True" and "False"
- 3. The hint for the student

Each **Concept Group** has some number of foils representing questions which are conceptually related. Option Response Problem Templates are available for 4 and 8 Concept Groups. When the Option Response problem is presented to a student, the LON-CAPA system will randomly select one foil from each Concept Group and present it to the student. In order to receive credit for the problem, the student must select the corresponding option from the drop-down box for each given foil.

4.3.2 Example: Concept Group

A Concept Group may contain the following True/False questions:

- "Mark Twain" is the pen name of Samuel Clemens.
- Mark Twain wrote "The Call of the Wild".
- Mark Twain wrote "Huckleberry Finn".
- Mark Twain spent most of his life in the Congo.

For each foil, the author marks it **true** or **false**. When the student logs on and attempts to answer this question, the student will see only one of the four choices for that Concept Group. They then go on to do the remaining three to seven Concept Groups in this question before submitting their answer.

4.3.3 Example: Matching Problem

Option Response problems can be used as matching problems.

For example, you might want to ask the student to match musical compositions with their composers. You could create an Option Response problem with 4 Concept Groups, and place the following four foil groups each in its own concept group:

- Claire de Lune, Ballade (Debussy)
- The Pastoral Symphony, The Ninth Symphony (Beethoven)
- Sleeping Beauty Suite, The Dance of the Sugar Plum Fairies (Tchaikovsky)
- Slavonic Dances, New World Symphony (Dvorak)

You could then add the following options to the option list:

- Debussy
- Beethoven
- Schubert
- Tchaikovsky
- Dvorak

The same answers can be used more than once, or not at all, as you see fit. It is conventional to place such a warning in the **Text Block** describing the problem to the students.

4.4 String Response Problems

String Response problems allow the student to submit a string of characters for the answer. Examples of String Response questions are vocabulary tests, short answers and chemical formulas.

Note that it is easy to abuse String Response problems. For instance, consider the question "Who wrote 'Huckleberry Finn'?" If you tell the system the answer is "Mark Twain", and a student answers "Twain", the system will mark it wrong. If they answer "Samuel Clemens", then the student will definitely get it wrong. There is some room for flexibility in the string processing, but it can be difficult to get it all correct. Before you use a String Response problem, be sure you can easily characterize correct answers.

4.5 Numerical Response Problems

Numerical Response problems are answered by entering a number and (optionally) a unit, such as 2.5 m/s². Tolerance and required significant digits can be specified as well.

4.6 Formula Response Problems

Formula Response problems ask the student to type in a formula as an answer. If the answer is $2x^2 + 4$, the student is allowed to type " 2^*x^*x+4 ", " $x^*x + x^*x + 4$ ", " $2^*x^2 + 14 - 10$ ", or any other equivalent expression. Formula Response problems have many of the same characteristics of Numerical Response problems, including the ability to run scripts, dynamically generate answers, etc.

4.7 Math Response Problems

Math Response is a way to have a problem graded based on an algorithm that is executed inside of a computer algebra system based on an algorithm written by the problem author. It is extremely powerful, as it tests answers for conditions rather than agreement with a particular correct answer. An unfortunate byproduct, however, is that it cannot be analyzed by several of the LON-CAPA statistics tools.

4.8 Custom Response Problems

Custom Response is a way to have a problem graded based on an algorithm constructed in the perl script. The use of this response type is generally discouraged, since the responses will not be analyzable by the LON-CAPA statistics tools.

4.9 Function Plot Response Problems

A **Function Plot Response** problem requires that the student create a plot that matches specified criteria. Examples can be functions that have certain slopes, curvature, maxima or minima at specified independent coordinate values. The students create their answer by dragging the curves and adjusting the slopes.

5 Authoring Content in LON-CAPA

LON-CAPA internally recognizes the types of resources by the filename extension. Within the authoring space, there are two methods to create a new resource:

- If you are using Inline Menus, you may use the dropdrown menu on the right of the authoring screen to indicate the type of resource you want to create as shown in the figure 5. The filename extension will be specified when you select the resource type. This method is best for new authors.
- Or, you may type the full url of the new resource in URL bar of your browser. You must use a valid file extension. LON-CAPA will recognize the new resource type by the filename extension and present you the appropriate menus to create your resource. This method is appropriate for advanced authoring.

5.1 Authoring and Editing Content Pages

Many users use stand-alone editing programs such as Dreamweaver to create HTML files. To upload HTML files generated with such tools, you can use the **Browse...** button in the Authoring Space, locate your HTML file, and use the **Upload File** button to upload a HTML file in LON-CAPA. Remember to upload any local graphics your generated web pages may have referenced using similar procedures. The links to graphics in your html page must match the relative locations for the uploaded files.

To create a new html page using the Inline Menus, browse to the desired folder using the folder navigation links in the lower part of the authoring screen. Then select 'HTML file' from the new content dropdown menu on the right of the authoring space page as shown in the dropdown menu of the figure 5.

When you edit a web page, you will be presented with a plain text editor as shown in the figure 7. Clicking the link for the Rich Formatting displays the HTML WYSIWYG editor (CKEditor) with buttons to help you create html entities with correct tags as shown in the figure 8. If the rich layout is not as you expect, look for the button to view/edit the source, and then manually make adjustments to the html tags. Note the three buttons in the CKEditor toolbar (ringed in the figure 8), which can be used to (a) include an image, (b) add a chemical equation, or (c) add a math expression or equation. Buttons are also provided to create/edit links. (See: Creating Equations section 5.1.1 for information about creating and editing math equations.)

If you use the Image button to include graphics you will either the location of the file in the URL box. The location can either be relative to the current file, or can be an absolute URL for the location of a published file (i.e., /res/domain/username/path/filename). When you are done editing the HTML file, you will need to upload the graphics file, if it does not already exist and publish it to the content repository.

Note the convenient help links for **Greek Symbols**, **Other Symbols**, **Output Tags**, **and Languages** immediately above the editor in the figures. Also note the link to check spelling below the editor.

The URL of the page in the root of your Authoring space would look something like http://(your library server)/priv/domain/username/new_resource.html.

5.1.1 Creating Equations

LON-CAPA renders math using LaTeX. LaTeX equations can be entered directly in the source with the text editor, within <m>\$ \$</m> tags. When the browser has support for Java applets, the DragMath editor can also be used to generate LaTeX. To start DragMath in the text editor, insert the cursor at the desired equation location and click on the 'Edit Math' button. At the bottom of the DragMath pop-up is a 'Render LaTeX' button that will insert the DragMath expression as LaTeX within <m>\$ \$</m>

The DragMath editor may not offer the template that you need, or the expression may not appear as you expect. The most powerful method of entering math or touching up DragMath output is to learn about the LaTeX syntax. An Internet search for "LaTeX math quick reference" will result in many resources.

To create equations in CKEditor (the WYSIWYG editor launched with the "Rich formatting" link), you can use the Σ button. It requires knowing the LaTeX syntax, but provides a real-time preview. Equations can be edited with a double-click on the rendering.

Within the <m> tag, additional tags control the display of LaTeX math. The \$ open and closing syntax will create an inline equation. To create an equation in a separate paragraph, use double signs, \$\$. Alternative notations are also accepted, \(opening with \) closing can be used for an inline equation, and \[opening with \] closing results in a separate paragraph. The \$ and \$\$ methods are recommended as "LaTeX robust" and the \(and \[methods are considered "LaTeX fragile." The robust methods should be used if the fragile methods result

in unexpected behavior.

Some simple sytax from common LaTeX math:

- \frac{numerator}{denominator} results in *numerator*/*denominator*
- $\hat{}$ superscript, e.g. x^2 results in x^2
- _ subscript, e.g. x^2_i results in x_i^2
- use { and } as delimiters, e.g. x_{-} {upper} for x_{upper}

See **m** tag in Output Tags 15.6 for more information.

5.1.2 How to Edit Existing Content Pages

You may edit any Content Pages that have been created. To edit Content Pages:

To our content rages.

- 1. Navigate to the folder with the HTML file.
- 2. Click on the link for the name of the HTML file to edit.

5.2 Authoring Problems Using LON-CAPA

When you create a new problem as in the figure 5, LON-CAPA will offer to you example templates that are highly recommended for beginners. A subset of the problem templates is illustrated by the multiple choice selections shown in the figure 9. Click the **Example** link next to menu item to see an example problem. Once you make a selection, you can use the template and edit the content to convert the template into your own problem. By default, the template problem will be displayed in the problem testing mode with a header shown in the figure 10. The problem statement (not shown here) appears below the testing menu. The menu will be described later. Click the **Edit** button in the lower left to open the colorful editor. The EditXML button is for advanced users. An additional editor (named Daxe) may be available in your Authoring Space. Daxe uses an XML schema, configuration file and user interface code for the markup language used by LON-CAPA documents.

The menu for the colorful editor is shown in the figure 11. The button functions are:

- Discard Edits and View return to the testing menu without saving
- EditXML switch to the XML Editor
- Edit with Daxe switch to the Daxe Editor
- Undo forget last edits
- Save and Edit Save and continue editing in the colorful editor
- Save and View Save and return to the testing menu

Edit EditXML		

Figure 10: Problem Testing Menu

An example of the colorful editor is shown in Figure 13. Each box in the colorful editor has a purpose, and the boxes are colored by their purpose. Note that the current editor includes more space between the blocks than shown in many of the figures in this manual. Also, the newer editor has an 'Insert' dropdown box between blocks so that you can insert content easily.

While several problem types are covered in this manual, in LON-CAPA all problems involve similar XML elements. The menu for the XML editor is shown in the figure 12. Note that the editor includes help links at the top. The **Edit** button starts the colorful editor. The **Edit Math** button adds latex math. The other buttons are the same as the colorful editor buttons. If you find yourself uncertain about the name or function of an LON-CAPA xml tag, consult the reference in section 15.

The problem editor gives you a testing area where you can try your problems out, with several different randomizations by varying the **Random Seed**. If you answer a problem correctly and can no longer enter new answers, you can get the answer field back by hitting the **Reset Submissions** button.

Problems also may appear differently after the answer date, or on an exam. The editor

provides dropdown selectors to view problems with such conditions set.

5.3 General Problem Editing

The following capabilities are available in all problem types:

5.3.1 Authoring Surveys

Surveys are created by authoring a conventional problem, such as a Radio button or Option problem. During the authoring process, you will need to select one of the foils as "correct". Which foil is set to "correct" will not matter, however; that setting will be ignored when you implement the survey.

Within the course environment, to add a survey to the course, insert the "problem", and then set the parameter for "Question Type" to "Survey", "Survey with Credit", or "Anonymous Survey". To evaluate the survey, you will perform analysis using Reports -> Survey Results or Statistics and Analysis -> Detailed Problem Analysis.

The results examined with either tool will be displayed sorted by foil name, so take some care while authoring to name the foils. For example "Foil10" appears before "Foil2" alphabetically, so your survey may easier to interpret if you insert a zero before single digits, such as "Foil02" and "Foil10" which will sort as expected.

5.3.2 Adding Picture

To add a picture to a problem, the picture must first be uploaded to your authoring space, then published. Then, in the text area of your problem, add the following:

where DOMAIN is the domain the picture is in, AUTHOR is the person who published the picture, and the rest is the standard path to the picture.

It is also possible for advanced users to use a script variable in the place of the picture URL, like this:

```
<img src="$picture" />
```

and use the string variable **\$picture** in the script of the problem to select from several possible pictures. If you do this, you will need to **Edit XML** for the problem and add the various graphics used in the problem to the *<allow>* tags on the bottom.

When print resources with pictures, LON-CAPA will automatically convert graphics in EPS files. (EPS is a graphics format designed for printing.)

The automatic conversion of a web graphic to an EPS file will sometimes look blocky, because paper has a much higher resolution then the web. If you would like to provide LON-CAPA with an EPS file to use while printing for a given graphic file, upload your EPS file into your authoring space with the same name as the .gif, .jpg, or other web graphic, except ending with the extension ".eps". When you publish the file, LON-CAPA will automatically use it in place of the web image file when printing.

For instance, if you have a graphics file my.image.gif, you can upload an EPS file named my.image.eps.

5.3.3 Dynamic Plots

Dynamic Plots can be generated from calculations based on random numbers. The student can be asked to respond to the plot. Another option is to use student input to display a graphical result to students based on an input that they provide.

5.3.4 Importing Testbanks

The following requirements must be met to ensure that you will succeed in building LON-CAPA problem files from a file containing testbank questions.

- 1. The uploaded testbank file containing questions and answers must be either plain text, rich text format (RTF), or a web page (i.e., HTML format). Testbank files in RTF and HTML formats may contain images. If conversion to LON-CAPA fails for RTF or HTML formats, re-saving the testbank file from the application originally used to generate it in plain text, and re-uploading the file to LON-CAPA may solve the problem (albeit with the loss of formatting information).
- 2. All questions must occur before any of the answers. Each question should begin on a new line starting with a number followed immediately by a space, a period, or enclosed in parentheses, i.e., 1, 1, (1), 1), or (1. If you use a word processor to create the testbank questions you must disable auto-formatting of lists, otherwise the formatting will not conform to the new line requirement.
- 3. One or more correct answers need to be provided for all questions (although the answer text may be blank for *essay* questions). Each answer should begin on a new line using the same numbering scheme as used for the questions, and all answers must occur after all the questions.
- 4. *Multiple choice* and *multiple answer correct* questions should consist of (i) the question number followed by (ii) a question stem beginning on the same line and (iii) two or more foils, with each foil beginning on a new line and prefixed by a unique letter, or

Roman numeral, listed in alphabetic or numeric order, beginning at a (alphabetic) or i (Roman numeral), followed by a period, or enclosed in parentheses, i.e., a., (a), i., or (i)

5. If *fill-in-the-blank* or *multiple answer* questions have more than one correct answer, each answer should appear in a comma-, tab-, space-, or new line-delimited list. For a *ranking/ordering* question, the "answer" should contain the foil identifiers correctly ordered in a similarly delimited list. If two or more foils have the same ranking, they should occur together, with an equals sign separating equally ranked foils [e.g., (b),(e)=(a),(d),(c)]

5.3.5 Answer Display Overview

Several xml tags are available to provide student guidance during problem display and also after the answer date. These include <notsolved>, <preduedate>, which are useful when the students are working a problem, and <solved>, <postanswerdate>, which are helpful in providing feedback. The content in the xml tag <postanswerdate> is suppressed until after the answer date.

Answers are typically not displayed to the student when they submit an answer to a problem, unless their answer is correct. When the problem is assigned in a course, a parameter for the 'answer date' must be set such that students will see answers displayed when they revisit the problem after that date. The answer date is distinct from the due date which can also be set when a problem is assigned.

Suppose you want the answer displayed as soon as the student finishes the problem rather than waiting until the answer date. For example, this may occur in a multipoint problem where you want the students to see the correct answer for one part before proceeding to the next part. If you would like the computer answer to be displayed after the student answer is correct, or the maximum number of tries has been reached, this can be achieved by setting the parameter **problemstatus** = answer. Using the colorful editor, the parameter can be inserted WITHIN the problem part, but BEFORE the response tag (e.g. numericalresponse). For example:

The options for the problemstatus are: "yes" - shows correct or incorrect only; "answer" - shows computer answer as described above; "no" - don't show correct/incorrect feedback; "no_feedback_ever"- supresses all feedback.

If you want to provide additional explanation in addition to the answer as soon as the maximum tries allowed for the part have been reached, include a conditional block in the

problem part, and set the condition for the part to evaluate to true when the problem is either correct, no tries remain, or it is post-answer date.

To achieve this behavior, add a call to the LON-CAPA function &check_status('partid') for each part to the script block, and set a scalar to the value returned for each part, then use that scalar in the conditional block, e.g.,

```
<script type="loncapa/perl">
# for part: a
$status_a = &check_status('a');
# other computations
</script>
<part id="a">
<block condition="$status_a">
<block condition="$status_a"</block condition="$st
```

6 Authoring Radio, Option, String Response Problems

6.1 Authoring Radio Response Problems

To create a **Radio Response** problem, create a new resource as described in section 5. This is a "problem" resource so the URL must end in ".problem". You should see a screen as in figure 5. You will need to specify the question text and foil statements.

- 1. Select a radio response template from the menu. You will be presented a form such as in the figure 13.
- 2. In the **Text Block** at the top of the problem, remove the sample text and type the question for your problem. Ex: "What is two plus two?"
- 3. Locate the **Response: One of N statements** element. In the **Max Number of Shown Foils** text box, place the number of foils you wish to display to the student.
- 4. Locate Foil 1. Remove the text that is in the text box and put the *correct answer* for the problem in the Text Block. For example, "Four." Make sure this is set to true in the Correct Option field.
- 5. Below it, you will see Foil 2. Remove the text in the text box and put an *incorrect* answer for the problem. Ex: "Purple." Make sure this is set to false in the Correct Option field.

Figure 14: Hint Element

- 6. Repeat the previous step until you've filled in all of the other incorrect answers you wish to offer the students.
- 7. Once you've filled in all of the incorrect answers, delete any extra foils or change the **Correct Options** on the other foils to **Unused**.
- 9. Scroll down to the Hint element. See the figure 14 Type some text that will help students when they answer incorrectly. You may delete the hint by selecting **Yes** from the **Delete** drop-down box.
- 10. Click the **Submit Changes** button located at the top of the frame. If you do not do this, your changes will not be saved.

The **Correct Option** drop down box controls whether or not a given answer will be accepted as a correct answer. If it is set to **true**, that answer will be considered a correct answer. Any number of foils can be marked **true**, but only one will be shown to any given student. If it is set to **false**, it will be considered an incorrect answer. If it is set to **Unused**, the system will not use that foil.

Example code for a radiobutton response:

```
<radiobuttonresponse randomize="yes">

<foilgroup>

<foil location="random" value="true" name="right1">

<startouttext />This is the right answer.<endouttext />

</foil>

<foil location="random" value="false" name="wrong1">

<startouttext />This is the first wrong answer.<endouttext />

</foil>

<foil location="random" value="false" name="wrong2">

<startouttext />This is the second wrong answer.<endouttext />

</foil>
```

</foilgroup>

</radiobuttonresponse>

See section 15.1.4 for more information on <radiobuttonresponse>.

6.1.1 Randomization

LON-CAPA will randomize the choices presented to each student and the order they are presented. If you wish to present a random set of incorrect answers, create more foils than you wish to display, and then set the **Maximum Number of Shown Foils** to a value less than the number of foils created. If you wish to present each student the same choices, make sure the **Maximum Number of Shown Foils** box contains a number greater or equal to the number of foils that you created, which will force them to all be displayed.

6.2 Authoring Option Problems

To create an Option Response problem, create a new resource as described in section 5. This is a "problem" resource so the URL must end in ".problem". You should see a screen as in figure "Option Response Editor".

- 1. In the drop-down option box as seen in figure 5, select **Option Response Problem** with *N* **Concept Groups**, where *N* is the number of Concept Groups you wish the problem to have, and click the **New Problem** button.
- 2. Click the **Edit** button above the sample problem to enter edit mode. You should see the Option Response page open up.
- 3. Replace the text in the **Text Block** with text that explains the conditions for your problem.
- 4. Locate the **Max Number of Shown Foils** element and type a number from 1 to 8 to display that number of questions. You cannot display more than one foil from each concept group, so this option will only reduce the number of foils displayed, if it is less than the number of concept groups in your Option Response problem.
- 5. Now you must define the options the students can select. For each option you wish to add to the Option Response question, type the option into the **Add new Option** box in the **Select Options** section, then hit the **Save Changes** button. If you do not hit the **Save Changes** button, your option will not be selectable below. (You can delete unwanted options in the last step.)
- 6. Now, you need to define the question foils. Look for the foil with the name "One". Type the question into the text box and select the correct option for that question from the **Correct Option** drop-down menu. Click **Submit Changes** to save this question foil. Repeat this step for all remaining foils.

Figure 15: Option Response Editor

- 7. Locate the foils that are not being used. In their **Delete** menus, set the value to **Yes**. Once you've set the Delete menu value correctly for all the foils, click the **Save Changes** button.
- 8. In the Hint area, provide a helpful hint for users who get the problem incorrect, and click the **Save Changes** button.
- 9. Make sure all the options you want to delete are not used for any of your foils. If a deleted option is used in a foil, it will appear in a text box in the **Correct Option** area for that foil. To make the drop-down box reappear, type an option already defined in the **Select Options** field, and hit **Submit Changes**. A drop-down box will reappear. To delete the irrelevant options from the Option Response question, select that option from the **Delete an Option** drop down, and hit the **Save Changes** button. Do this for each option you wish to remove.

6.3 Simple Option Response: No Concept Groups

If you select **Simple Option Response** from the drop-down box, you will get a template that will allow you to enter up to eight foils with no grouping. The system will randomly mix these foils when presenting them to the student. You can have more foils than the **Max Num of Shown Foils** so that each student will not have the identical foils.

Figure 16: String Response Editor

6.4 Authoring a String Response Problem

To create a **String Response** problem, create a new resource (described in 5.2. This is a "problem" resource so the URL must end in ".problem".

- 1. In the drop-down option box as seen in the figure 5, select **String Response Problem**, and click the **New Problem** button.
- 2. Click the **Edit** button above the sample problem to enter edit mode. You should see the String Response editor page open up, which should look something like what you see in the figure 16.
- 3. Clear the text from the **Text Block** at the top of the problem, and type in your problem.
- 4. In the **Answer Box**, type the correct answer.
- 5. Select the answer condition from the drop-down. There are three cases to choose from:

- (a) **cs**: This means "Case Sensitive". For example, this is useful in chemistry, where HO and Ho are completely different answers. The student must match the case of the answer.
- (b) **ci**: This means "Case Insensitive". The system does not use the case of the letters to determine the correctness of the answer. If the correct answer is "car", the system will accept "car", "CAR", "Car", "caR", etc.
- (c) mc: This means "Multiple Choice". The student's answers must contain the same letters as the question author's, but order is unimportant. This is usually used to give a multiple choice question in the question's **Text Block**, which may have several correct parts. If the author sets the correct answer as "bcg", the system will accept "bcg", "cbg", "gcb", etc., but not "bc" or "abcg".

It is conventional to inform the students if the problem is case sensitive, or that the order of the answers doesn't matter.

- 6. Optionally, locate the **Single Line Text Entry Area** block and set a length in the Size box. This will only affect the size of the box on the screen; if you set the box size to 2, the student can still enter 3 or more letters in their answer.
- 7. Scroll down to the **Hint** element, and type some text that will help students when they answer incorrectly, or delete the hint by setting the **Delete** field to **Yes**.
- 8. Click the **Submit Changes** button.

7 Authoring Numerical, Formula, Custom Response Questions

7.1 Authoring Numerical Response and Formula Response Problems

Numerical Response problems are answered by entering a number and an optional unit. For instance, a numerical response problem might have an answer of $2m/s^2$. Formula Response problems are answered by entering a mathematical formula. For instance, a formula response problem might have an answer of $x^2 + 11$. The answer may be in any equivalent format. For instance, for $x^2 + 11$, the system will also accept x * x + 11 or $x^2 + 21 - 10$.

Numerical Response problems are very powerful. In fact, they are so powerful it would be impossible to fully explain what is possible in a simple document. This chapter will focus on getting you started with Numerical Response problems and show you some of the possibilities, with no prerequisite knowledge necessary. The more you learn, the more you will find you can do.

If you like, you can follow this chapter as its own tutorial. Create a Numerical Response problem using the instructions in the "Authoring Content in LON-CAPA" section 5, ending your resource name with ".problem", and create a new **Simple Numerical Response** problem.
7.2 The Parts of a Numerical Response Problem

A Numerical Response problem has seven major parts by default:

- 1. The **Script** is the heart of advanced Numerical Response problems. It can be used to decide some of the parameters of the problem, compute the answer to the problem, and do just about anything else you can imagine. The Script language is **Perl**. You do not need to know Perl to use the **Script** block because we will be stepping through some advanced examples in this chapter, but knowing Perl can help.
- 2. Like other problem types, the **Text Block** is used to display the problem the student will see. In addition, you can place variables in the **Text Block** based on computations done in the **Script**.
- 3. The **Answer** is the answer the system is looking for. The answer can use variables calculated/defined in the problem's **Script** block, allowing the answer to be determined dynamically (including randomization).
- 4. A **tolerance** parameter determines how closely the system will require the student's answer to be in order to count it correct. The tolerance will default to zero if it is not defined. The tolerance parameter should always be defined for a numerical problem unless you are certain only integer answers are generated from your script and you want students to reply with exactly that integer.

There are three kinds of tolerance. For some answer A and a tolerance T,

- (a) an **Absolute** tolerance will take anything in the range $A \pm T$. So if A = 10 and T = 2, then anything between 8 and 12 is acceptable. Any number in the tolerance field *without* a % symbol is an absolute tolerance.
- (b) a **Relative** tolerance will take anything in the range $A \pm aT$, where T is interpreted as a percentage/100. Any number in the tolerance field *followed by* a % symbol is a relative tolerance. For example, a = 10 and t = 10% will accept anything between 9 and 11.
- (c) a tolerance that is a calculated variable (identified by \$ sign as the first character). For example, if an answer is \$X, and for a student possible values range from -\$X1 to +\$X1, you could choose T = \$tolerance = \$2X1/100\$; acceptable answers would then be from <math>\$X \$tolerance to \$X + \$tolerance\$. (This is especially useful when answers close to zero are possible for some students)

Figure 17: Numerical Response editor

Some care is necessary when setting the display format of the computer answer. Before testing the tolerance, LON-CAPA converts the computer answer, as generated in the script block, according to the format attribute in the numerical response tag.

Next, the formatted comptuer answer is "graded" relative to the significant figures parameter, if it is set (see section 5. If that test was passed, then a numerical comparison of the Computer's answer is made with the range of values:

(\$computerAnswer - \$tolerance) < \$formatted computerAnswer < (\$computerAnswer + \$tolerance)

If the \$formatted computer Answer satisfies the permitted range, then "correct" is returned for the computer answer. It is good idea to test multiple randomizations to make sure that your tolerance is compatible with the display format.

5. A significant figures specification is an optional setting that tells LON-CAPA how many significant figures there are required for the answer, as either a single number, e.g. 3, or a range of acceptable values, expressed as **min,max**. The significant figures field can be omitted if you do not want to constrain the number of significant digits in the student answers.

The system will check to ensure that the student's answer contains the required significant digits, useful in many scientific calculations. For example, if the computer answer is "1.3", and the problem requests three significant digits, specified by (entered without quotes) "3", the system will require the students to type "1.30", even though numerically, "1.3" and "1.30" are the same. A significant figure specification of (entered without quotes) "3,4" means both "1.30" and "1.300" are acceptable.

Authors should be clear in the problem statements to tell students the required number or range of significant figures. If the student response does not contain the correct number of significant digits, the LON-CAPA response will tell students to increase or decrease the digits in their response, but it will not tell them how many digits to use. These responses do not use up the number of trials, but such responses are frustrating for students. If you would like to ensure that at least three significant digits are used, then a specification such as 3,15 ensures at least three digits are used, but will quietly accept up to 15.

Note that care must be used when using formatted computer answers together with a significant digit specification. You must ensure that the formatted answer provides enough significant digits. To test the formatted answer, LON-CAPA converts the computer answer, as generated in the script block, according to the format attribute in the numerical response tag, e.g. 3f. Then LON-CAPA separately applies that number of significant figures to the computer answer, and if that result falls outside the range specified in the significant digit parameter, it "grades" the computer answer as SIG_FAIL (i.e., not correct). It is a good idea to use the problem testing environment to test plenty of different randomizations to make sure that your format and sig digits parameters are compatible. This helps ensure that the formatted answer has enough significant digits.

- 6. The **Single Line Text Entry** area, as in other problem types, allow you to manipulate the text entry area the student will see.
- 7. Finally, the **Hint** should contain text which will help the students when they answer incorrectly.

7.3 Simple Numerical Response Answer

Along with showing the Numerical Response editor, figure 17 also shows the parameters for one of the simplest possible types of numerical responses. The **Text Block** has the problem's question, which is the static text "What is 2 + 2?" The **Answer** is "4". The **Hint** has been set to something appropriate for this problem. Everything else has the default values from when the problem was created.

If you create a problem like this, hit **Submit Changes**, then hit **View** after the changes have been submitted, you can try the problem out for yourself. Note the last box in the HTML page has the answer LON-CAPA is looking for conveniently displayed for you, along with the range the computer will accept and the number of significant digits the computer requires when viewed by an **Author**.

As you're playing with the problem, if you use up all your tries or get the answer correct but wish to continue playing with the problem, use the **Reset Submissions** button to clear your answer attempts.

7.4 Simple Script Usage

Totally static problems only scratch the surface of the Numerical Response capabilities. To really explore the power of LON-CAPA, we need to start creating dynamic problems. But before we can get to truly dynamic problems, we need to learn how to work with the **Script** window.

A script consists of several **statements**, separated by **semi-colons**. A **statement** is the smallest kind of instruction to the computer. Most problems will be built from several statements.

A script can contain **comments**, which are not interpreted as statements by the computer. Comments start with # and go to the end of that line. Thus, if a line starts with #, the whole line is ignored. Comments can also begin in the middle of a line. It is a good idea to comment more complicated scripts, as it can be very difficult to read a large script and figure out what it does. It is a *very* good idea to adopt some sort of commenting standard, especially if you are working in a group or you believe other people may use your problems in the future.

• One of the simplest statements in LON-CAPA is a **variable assignment**. A **variable** can hold any value in it. The variable name must start with a **\$**. In the **Script**, you need to assign to variables before you use them. Put this program into the **Script** field of the Numerical Response:

\$variable = 3;

This creates a variable named **variable** and assigns it the value of "3". That's one statement.

Variable names are *case sensitive*, must start with a letter, and can only consist of letters, numbers, and underscores. Variable names can be as long as you want.

There are many variable naming conventions, covering both how to name and how to capitalize variables¹. It is a good idea to adopt a standard. If you are working with a group, you may wish to discuss it in your group and agree on a convention.

If you **Submit Changes** and **View** the problem, you will see nothing has changed. This is because in order for a variable to be useful, it must be used. The variable can be used in several places.

7.4.1 Variables in Scripts

Variables can be used later in the same script. For instance, we can add another line below the **\$variable** line as such:

\$variable2 = \$variable+2;

Now there is a variable called **\$variable2** with the the number "5" as its value.

Variables can also be used in *strings*, which are a sequence of letters. The underlying language of the script, Perl, has a very large number of ways of using variables in strings, but the easiest and most common way is to use normal double-quotes and just spell out the name of the variable you want to use in the string, like this:

\$stringVar = "I have a variable with the value \$variable.";

This will put the string "I have a variable with the value 3." into the variable named "stringVar".

If you are following this chapter as a tutorial, add the previous two lines to your **Script** and submit the changes for the problem. There's no need to view it; there's still no visible change.

7.4.2 Variables in the Text Block

Once you've defined variables in the **Script**, you can display them in the **Text Block**. For example, using the previous three-line script we've created so far, you can place the following in the **Text Block**:

```
See the 3: $variable<br />
See the string: <b>$stringVar</b><br />
```

¹The author favors capsOnNewWords. Some people use underscore_to_separate_words. Many use uppercase letters to specify constants like PI or GOLDEN_MEAN. Some people always StartWithCapatalization. What's really important is to be consistent, so you don't have to guess whether the variable you're thinking of is coefFriction, COEF_FRICTION, or something else.

See the 3: 3
See the string: I have a variable with the value 3.
Submit Answer Tries 0/5

Figure 18: Result of Variables in the Text Block

a = -3.0; b = &sin(a);c = &pow(3.0, &abs(a));

Figure 19: Some Function Calls

If you save that and hit **View**, you should get what you see in figure 18. Note how the "\$variable" was turned into a 3, and the "\$stringVar" was turned into "I have a variable with the value 3."

If you are generating numbers using a formula which includes a division operation, it is advisable to format your output. For example, if variable=1/3, it will display with too many digits. You can adjust the format using the num output tag described in the Output Tags section 15.6

7.4.3 Variables in the Answer Block

You can use variables in the **Answer** part of the question. This means you can compute an answer to a question. If you set the answer of the question to be **\$variable**, **Save Changes** and **View** it, you'll see that LON-CAPA is now expecting "3.0" as the answer, plus or minus 5%.

7.5 Calling Functions

With variables, you can store strings or numbers. **Functions** allow you to manipulate these strings or numbers. Functions work like mathematical functions: They take some number of arguments in, and return one argument, usually a number or a string for our purposes. There are a lot of functions available in LON-CAPA. You can see a complete list in the Script section 16.1 and LON-CAPA function section 16.3.

For now, let's just look at some simple examples.

In the **Script** block, function names start with &. Some example function calls are shown above. You can see that functions can take either variables, numbers, or the results of other function calls as parameters. The &sin function returns the sine of an angle expressed in radians. &pow raises the first parameter to the power of the second parameter. &abs returns the absolute value of the argument.

Figure 20: Formula Response Problem

7.5.1 Numerical Response Randomization

If you're following this material and creating an example, click the button for a new random seed to generate other problem presentations.

7.6 Authoring Formula Response Problems

Formula Response problems authoring is illustrated by Figure 20. Note how the function is randomly generated, as well as the answer. Note that sampling is also available for evaluating answers. Sampling is a good alternative when students may give several equivalent forms that are difficult to compare in text. Clicking the help box next to the **Sample Points** field describes how to use sample points instead of a text comparison.

Figure 21: Slope Problem Parameters

7.7 Dynamic, Randomized Problems: Putting It All Together

Now you have all the tools to create those wonderful dynamic, randomized problems that you've seen in LON-CAPA. Consider a Numerical Response problem where the equations for two lines are randomly generated and the students are asked to find the intercept. Try filling out your problem with the parameters shown in Figure 21.

When creating randomized problems, you want to make sure that the problems always have an answer. Consider what might happen if two slopes are chosen, *both* with the expression &random(-1.0, 1.0, .2). One out of ten students would get a problem where both slopes were equal, which has either no solution (for unequal y-intercepts) or an infinite number of solutions (for equal slopes and y-intercepts). Both of these cause a division-by-zero error on the division that computes the answer. There are many ways to avoid this, one of the easiest of which is picking one slope negative and one positive. This same problem can show up in many other places as well, so be careful.

7.8 Units, Format

Numerical Response problems can require units. In the problem editing form, place the desired unit in the **Unit** field. A complete list of units is in the Physical Units section (20). The computer will accept the answer in any of its accepted unit formats. For example, if the answer to a problem is "1ft", the computer will accept "12in" as correct.

Additional units can be defined using the "customunits" parameter, which is a commaseparated list of unit conversions. For example

peck=2*gallon,bushel=8*gallon,gallon=4.4*L

would define the new units peck, bushel, and gallon. The last entry in a conversion chain always needs to be a unit that LON-CAPA already supports.

You can format the number displayed by the computer as the answer. For instance, if the answer is one-third, the computer will display that it computed ".3333333333" as the answer. If you'd like to shorten that, you can use the **Format** field. Format strings like "2E" (without the quotes) will display three significant digits in scientific notation. Format strings like "2f" will display two digits after the decimal point. Format strings like "2s" will round a number to 2 significant digits. For a summary of numerical format statements, see the **num** tag item in the Output Tags section (15.6).

7.9 For More Information

The full power of Perl is well outside the scope of this document. Looking in the function list in the section 16.3 can give you some ideas. O'Reilly has some good Perl books. Enter "perl" in the search box at http://search.oreilly.com.

If you need help, you might search the listserv at

http://mail.lon-capa.org/mailman/swish.cgi or consider joining the users listserv to ask other users for advice at http://mail.loncapa.org , or use the Help link to contact the Help desk. Often other users are quick to provide help.

Our advanced users often come to prefer the XML interface for the problems, available through the **EditXML** buttons. Covering the XML format is beyond the scope of this manual, but you can learn a lot by using the editor to make changes and seeing what happens to the XML. Supported XML tags are discussed in the Tags Used in XML Authoring section (15).

7.10 Formula Response

Formula Response problems have the same capabilities as Numerical Response problems, and add the ability to ask the student for a symbolic formula as an answer, instead of a simple number.

7.10.1 Sample Specifications

As you may know, it is extremely difficult to determine whether a given expression is exactly equal to another expression in general. For example, is $\sin 2x = 2 \sin x \cos x$? LON-CAPA has two ways of finding out if it is:

- algebraically, using a symbolic algebra system
- numerically, using sampling points

You need to determine which way is the safest in a given situation.

If you don't specify sampling points, the symbolic algebra system is used.

If you do specify sampling points, LON-CAPA uses them. If your answer and the student's answer agree at the sampling points within your given tolerance factor, the student's answer will be accepted. If the student's answer does not agree at the sampling points within your given tolerance factor, it will be rejected.

To specify where to sample the formulas for determining whether the student's answer is correct, you need to put a sampling specification in the **Sample Points** field. The sampling specifications take the following format:

- 1. A comma-separated list of the variables you wish to interpret,
- 2. followed by "@" (not in quotes),
- 3. followed by any number of the following two things, separated by semi-colons:
 - (a) a comma-separated list of as many numbers as there are variables, which specifies one sampling point, OR
 - (b) a comma-separated list of as many numbers as there are variables, followed by a colon, followed by another list of as many numbers as there are variables, followed by a #, followed by an integer.

The first form specifies one point to sample. The second form specifies a range for each variable, and the system will take as many random samples from that range as the number after the #.

For $2x^2 + 4$, with one variable "x", one could specify:

- "x@2", which will sample the answers only at 2. (This is generally a bad idea, as the student could get lucky and match at that point)
- "x@1:5#4" will takes 4 samples from somewhere between 1 and 5.
- "x@1:5#4;10" will takes 4 samples from somewhere between 1 and 5, and also sample at 10.

For $2x^2 + 3y^3 + z$, which has three variables, one could specify:

• "x,y,z@4,5,3:10,12,8#4;0,0,0", which take four samples from the box determined by the points (4, 5, 3) and (10, 12, 8), and also sample the point (0, 0, 0).

7.10.2 Formula Notes

- The formula evaluator can not handle things of the form "x + y". If you have a random variable that may be positive or negative (as in the example following this section), you can try wrapping the references to that variable in parentheses. As always, it is a good idea to try out several randomized versions of your problems to make sure everything works correctly.
- Never use relative tolerance in Formula Response problems. Relative tolerance is poorly defined in Formula Response problems. Always use absolute tolerance.

7.10.3 Example Formula Response

A very simple formula response problem:

• In the **Script**, place the following:

```
$slope = &random(-5.0,5.0,.5);
$yint = &random(-5.0,5.0,.5);
$answer = "$slope*x + ($yint)";
```

- In the **Text Block**, place the following: "For a line with slope \$slope and y-intercept \$yint, what is y equal to?"
- In the Answer, place the following: \$answer
- Set the Tolerance to .000001.
- Set the **Sample Points** to x@0;1;2;3.

7.11 Authoring Math Response Problems

Math response problems use a cas system to evaluate the student response. Which computer algebra system is to be used is specified in the cas argument of the mathresponse tag; both Maxima and R are supported. Maxima and R are also powerful stand-alone programs that can be installed on most operating systems. If you are interested in writing Maxima or R problems, it is a good idea to install a copy on your operating system to access help, learn syntax, and test your expected responses outside the LON-CAPA environment. See http://maxima.sourceforge.net/ or http://www.r-project.org/.

LON-CAPA will accept two pre-named arrays inside the answerblock for the computer algebra system: RESPONSE and LONCAPALIST. RESPONSE contains the student input by comman-separated entities, for example, if "3,42,17" is entered by the student, RE-SPONSE[2] would be 42. LONCAPALIST is built from the arguments passed in an array args which is assigned a array value from the script.

The answer tag contains the Maxima command (and syntax) that are passed to Maxima after the RESPONSE and LONCAPALIST values are substituted. (See example below). The answerdisplay variable contains what is displayed when the problem is in "Show Answer" mode. You will want to include this field so that the students can see the correct answer after the "Show Answer Date" configured when the problem is assigned in the course space. Also note the description in the postanswerdate tag that is displayed after the answer date.

The following example illustrates this.

```
<problem>
```

```
<script type="loncapa/perl">
a1 = random(-6, 6, 4);
a2 = random(-6, 6, 4);
n1 = random(3, 11, 2);
n2 = random(2, 10, 2);
$function = "$a1*cos($n1*x)+$a2*sin($n2*x)";
# reformat next two lines as single line if you copy/paste into a script

7.12 Custom Response Problems

Custom Response is a way to have a problem graded based on an algorithm. The use of this response type is generally discouraged, since the responses will not be analyzable by the LON-CAPA statistics tools.

For a single textfield, the student's answer will be in a variable \$submission. If the Custom Response has multiple textfields, the answers will be in an array reference, and can be accessed as \$\$submission[0], \$\$submission[1], etc.

The student answer needs to be evaluated by Perl code inside the < answer>-tag. Custom Response needs to include an algorithm that determines and returns a standard LON-CAPA response. The most common LON-CAPA responses are:

- EXACT_ANS: return if solved exactly correctly
- APPROX_ANS: return if solved approximately
- INCORRECT: return if not correct, uses up a try
- ASSIGNED_SCORE: partial credit (also return the credit factor, e.g. return(ASSIGNED_SCORE,0.3);)
- SIG_FAIL, NO_UNIT, EXTRA_ANSWER, MISSING_ANSWER, BAD_FORMULA, WANTED_NUMERIC, WRONG_FORMAT: return if not correct for different reasons, does not use up a try

The answerdisplay is shown instead of the student response in 'show answer' mode after the answer date. The following example illustrates this:

<problem>

```
<textline readonly="no" />
</customresponse>
</problem>
```

Full list of possible return codes:

- EXACT_ANS: student is exactly correct
- APPROX_ANS: student is approximately correct
- NO_RESPONSE: student submitted no response
- MISSING_ANSWER: student submitted some but not all parts of a response
- EXTRA_ANSWER: student submitted a vector of values when a scalar was expected
- WANTED_NUMERIC: expected a numeric answer and didn't get one
- SIG_FAIL: incorrect number of Significant Figures
- UNIT_FAIL: incorrect unit
- UNIT_NOTNEEDED: submitted a unit when one shouldn't
- UNIT_INVALID_INSTRUCTOR: the unit provided by the author of the problem is unparsable
- UNIT_INVALID_STUDENT: the unit provided by the student is unparasable
- UNIT_IRRECONCIBLE: the unit from the student and the instructor are of different types
- NO_UNIT: needed a unit but none was submitted
- BAD_FORMULA: syntax error in submitted formula
- WRONG_FORMAT: student submission did not have the expected format
- INCORRECT: answer was wrong
- SUBMITTED: submission wasn't graded
- DRAFT: submission only stored
- MISORDERED_RANK: student submitted a poorly order rank response
- ERROR: unable to get a grade
- ASSIGNED_SCORE: partial credit; the custom response needs to return the award followed by the partial credit factor
- TOO_LONG: answer submission was deemed too long

- INVALID_FILETYPE: student tried to upload a file that was of an extension that was not specifically allowed
- EXCESS_FILESIZE: student uploaded file(s) with a combined size that exceeded the amount allowed
- COMMA_FAIL: answer requires the use of comma grouping and it wasn't provided or was incorrect

8 Authoring Dynamically Generated Plots

The **gnuplot** LON-CAPA tag allows an author to design a plot which will be created programatically at the time when it is requested for display by a student. This is intended for use in homework problems where a distinct plot should be rendered for each student. It can be used in conjunction with a **script** tag to generate curve data for random plots. If you are using static data a dynamically generated plot is not appropriate because of the overhead associated with generating the plot. In that case, use a picture (see "Adding Picture" section 5.3.2).

The easiset way to create a template for a gnuplot tag is to use the colorful problem editor, and select **GnuPlot** from the **Insert** dropdown menu. Thereafter the boxes may be filled using this documentation to assist you. By default, only the parent **gnuplot** tag and the child **curve** tag are created by when the plot is inserted into a problem using the colorful editor. Other tags can be added to decorate and polish your plot using the **Insert**: dropdown provided by the colorful editor.

The following **gnuplot** parameters may be set:

- brief description of the plot This text is used as the alt value of the img tag used to display the plot on a web page.
- background color of image (xfffff) See the "Color Selection" section 8.4 for help on specifying colors.
- foreground color of image (x000000) See the "Color Selection" section 8.4 for help on specifying colors.
- height of image (pixels)
- width of image (pixels)
- Size of font to use "small", "medium", or "large". The font used for any text on the plot is set with this tag.
- Transparent image "Yes" or "No". If the image is transparent the background color will be ignored.
- Display grid "Yes" or "No".

- Number of samples for non-data plots If a function tag is used (see "Plotting Functions" section 8.1.2) to specify the **curve** (see "Specifying Curves to Plot" section 8.1), this indicates the number of sample points to use.
- Draw border around plot "Yes" or "No"
- alignment for image in html "Left", "Center", or "Right". This is the value used for the align parameter in the img tag which embeds the plot in the problem.
- Width of plot when printed (mm) The width in mm of the plot when it is printed. The default is approximately one half of a U.S. letter size page, 93 mm.
- Font size to use in TeX output (pts) The size in points of text on the graph when it is printed out.
- Plot type "Cartesian" or "Polar".
- margin width (pts) The left, right, top, or bottom margin width measured in points.
- Size of major tic marks The size of the larger tic marks on the plot border or axes, measured in graph units.
- Size of minor tic marks The size of the smaller tic marks on the plot border or axes, measured in graph units.

The parent gnuplot tag allows use of the following child tags (only the curve tag is added automatically when inserting with the colorful editor):

- **curve** (see "Specifying Curves to Plot" section 8.1)
- title, xlabel, and ylabel (see "Plot Labels and Key" section 8.2)
- key (see "Plot Labels and Key" section 8.2)
- label (see "Plot Labels and Key" section 8.2)
- axes (see "Plot Axes Details" section 8.3)
- tics (see "Plot Axes Details" section 8.3)

8.1 Specifying Curves to Plot

The **curve** tag is where you set the data to be plotted by gnuplot.

The following parameters may be present in the **curve** tag and allow access to most of the formatting parameters for a curve in gnuplot.

• color

The color of the curve on the plot. See "Selecting Colors" section 8.4.

• name

If a key is present, the name of the curve will appear with a sample of its line type.

• linestyle

See "Line Styles" section 8.1.3 for more information about the available line styles and their data requirements.

• linetype

The type of line. Current options include 'solid' and 'dashed'. At this time, all dashed lines draw with line width of '1' in web output. This parameter may not apply to all linestyles.

• linewidth

The thickness of the line drawn by plotting engine. This parameter may not apply to all linestyles.

• pointtype

This parameter may not apply to all linestyles.

• pointsize

This parameter may not apply to all linestyles. The size of the points, in pixels, present on the line. Some point types are not affected by this parameter.

• limit

This parameter controls the pont to fill for filled curves.

• arrowhead

For vector plots, controls where in the vector the arrow head(s) appear

• arrowstyle

For vector plots controls the fill style of the arrow.

• arrowlength

For vector plots determines the distance between the vector line end and the tip of the arrow.

• arrowangle

For vector plots, determines the angle the arrow branches make with the vector line.

• arrowbackangle

For vector plots, determines the angle the arrow lines that return to the main line from the branches make with the arrow branches.

There are two ways of entering the information to be plotted, which are accessed using the subtags of **curve**, **data** (see "Plotting Data Points" section 8.1.1) and **function** (see "Plotting Functions" section 8.1.2).

8.1.1 Plotting Data Points

The **data** tag is used to specify the values plotted in the **gnuplot** tag (see "Authoring Dynamically Generated Plots" section 8). The **data** tag is only used in the **Curve** tag (see "Specifying Curves to Plot" section 8.1).

The data must be either a perl array, @X, or a comma separated list, such as "0.5,0.9,1.5, 2.4" (without quotes). 'NaN' is a valid value. Note the the "Y" values are entered in a separate array.

The function and number of **data** tags required varies based on the line style (see "Data and Line Styles" section 8.1.3) chosen for the curve. Some linestyles require extra arrays for supplemental information. In all cases the first **data** tag will hold the "X" values and the second will hold the "Y" values.

All of the data sets in the **data** tag must have the same number of elements.

8.1.2 Plotting Functions

The **function** tag allows you to specify the curve to be plotted as a formula, instead of numerical data.

The function must be a mathematical expression. Use the independent variable "x" for cartesian plots and "t" for polar plots. Implicit multiplication is not accepted by Gnuplot. The following are examples of valid functions and invalid functions:

- sin(x)
- sin(2*x)
- sin(x**2)
- exp(x)
- 3*x**x
- exp(sin(2*x))
- sinh(x)
- sin(t)*cos(t) (polar plot only)

8.1.3 Data and Line Styles

Unless otherwise noted the linestyles require only 2 data sets, X and Y.

- lines Connect adjacent points with straight line segments.
- **points** Display a small marker at each point.
- linespoints Draw both lines and points.

Draws a small symbol at each point and then connects adjacent points with straight line segments.

- dots Place a tiny dots on the given points.
- steps Connect points with horizontal lines.

This style connects consecutive points with two line segments: the first from (x1,y1) to (x2,y1) and the second from (x2,y1) to (x2,y2).

• **fsteps** Connect data with horizontal lines.

This style connects consecutive points with two line segments: the first from (x1,y1) to (x1,y2) and the second from (x1,y2) to (x2,y2).

• histeps Plot as histogram.

Y-values are assumed to be centered at the x-values; the point at x1 is represented as a horizontal line from ((x0+x1)/2,y1) to ((x1+x2)/2,y1). The lines representing the end points are extended so that the step is centered on at x. Adjacent points are connected by a vertical line at their average x, that is, from ((x1+x2)/2,y1) to ((x1+x2)/2,y1) to ((x1+x2)/2,y2).

- errorbars Same as yerrorbars.
- xerrorbars Draw horizontal error bars around the points.

Requires 3 or 4 data sets. Either X, Y, Xdelta or X, Y, Xlower, Xupper. Xdelta is a change relative to the given X value. The Xlower and Xupper values are absolute grid coordinates of the upper and lower values to indicated with error bars.

• yerrorbars Draw vertical error bars around the points.

Requires 3 or 4 data sets. Either X, Y, Ydelta or X, Y, Ylower, Yupper. Ydelta is a change relative to the given Y value. The Ylower and Yupper values are the grid coordinates of the upper and lower values to indicate with error bars.

• xyerrorbars Draw both vertical and horizontal error bars around the points.

Requires 4 or 6 data sets. Either X, Y, Xdelta, Ydelta or X, Y, Xlower, Xupper, Ylower, Yupper. Xdelta and Ydelta are relative to the given coordinates. Xlower, Xupper, Ylower, and Yupper are the grid coordinates of the upper and lower values to indicate with the error bars.

• boxes Draw a box from the X-axis to the Y-value given.

Requires either 2 or 3 data sets. Either X, Y or X, Y, Xwidth. In the first case the boxes will be drawn next to eachother. In the latter case Xwidth indicates the horizontal width of the box for the given coordinate.

• vector Draws a vector field based on the given data.

Requires 4 data sets, X, Y, Xdelta, and Ydelta. The 'vector' style draws a vector from (X,Y) to (X+Xdelta,Y+Ydelta). It also draws a small arrowhead at the end of the vector. May not be fully supported by gnuplot.

8.2 Plot Labels and Key

Three of the more basic tags are **title**, **xlabel**, and **ylabel**. Their size and color depend on the values chosen for the font size and graph foreground color specified in the **gnuplot** tag. The figure below shows the locations of the various labels.

The **key** tag causes a key to be drawn on the plot when it is generated. The key will contain an entry for each **curve** which has a name (see "Specifying Curves to Plot" section 8.1).

The key is the color of the foreground of the plot, specified in the **gnuplot** tag (see "Authoring Dynamically Generated Plots" section 8).

The **label** tag allows the author to place text at any position on the plot. There may be many **label** tags on one plot and all the labels which fall within the plot will show. The color used will be to foreground color of the plot and the font will be the size specified for the plot, both of which are set in the **gnuplot** tag (see "Authoring Dynamically Generated Plots" section 8).

- justification of the label text on the plot "left", "right", or "center".
- rotation of label (degrees)
- x position of label (graph coordinates)
- y position of label (graph coordinates)

The text to be placed on the plot must be entered as well.

8.3 Plot Axes Details

The **Plot Axes** tag allows you to specify the domain and range of the data to display. It is closely tied with the **Plot Ticks** 8.3 tags, which specify where the gridlines are drawn on the plot. The **Plot Axes** tag sets the following parameters:

The color of grid lines

If the "Display Grid" parameter of the Gnuplot tag is set to yes, the grid will be displayed in the specified color. Hexadecimal notation is used to specify the color (see Color Selection section 8.4).

The view of the graph shown

The viewing rectangle of the graph is set with the following parameters:

- minimum x-value
- maximum x-value
- minimum y-value
- maximum y-value

See also the Plot Ticks section 8.3 and the general Gnuplot help section 8.

The **xtics** and **ytics** tags can be inserted by selecting the **Plot tics** item from the insert selection list of the **gnuplot** tag.

The **xtics** and **ytics** tags have identical structure and the description presented here applies to both.

The tics tags allow specification of the following attributes:

• Location of major tic marks "Border" or "Axis". Tic marks can be placed on the border or on the axes. The images below illustrate the effects of each of these options.

• Mirror tics on opposite axis? "Yes" or "No". If the location of tic marks is set to "border" this parameter determines if they are shown on both the top and bottom or right and left sides of the graph. The "mirror" tic marks are unlabelled.

• Start major tics at

The point in graph coordinates which to start making major tics. This may be less than or greater than the lower limit for the axis.

• Place a major tic every

The span, in graph coordinates, between each major tic mark.

• Stop major tics at

This may be less than or greater than the upper limit for the axis.

Number of minor tics between major tic marks

The number of subdivisions to make of the span between major tic marks. Using a value of "10" leads to 9 minor tic marks. The example below uses a value of "5" to produce 4 tic marks.

• rotate

For output devices that support it, the **rotate='1'** attribute rotates the tic label. This is most useful with large lables defined by the **tic** tag described below.

In addition to specifying regular tic intervals via the attributes of the **xtics** and **ytics** you can specify arbitrary tic locations by enclosing **tic** tags within the body of these tags. Each **tic** tag requires the **location** attribute which specifies the location of a tic on the axis. The body of the tag contains the label of that tic.

The **xtic** or **ytic rotate** attribute can rotate the label text if the output device supports text rotation. If **tic** tags are embedded within the **xtic** or **ytic** tags attributes of those tags that specify tic boundaries and interval are ignored. Here's an example of an X axis tic specification in months of the year:

```
...
<xtics rotate='on'>
    <tic location='1'>January</tic>
    <tic location='2'>February</tic>
    <tic location='3'>March</tic>
```

```
<tic location='4'>April</tic>
<tic location='5'>May</tic>
<tic location='6'>June</tic>
<tic location='7'>July</tic>
<tic location='8'>August</tic>
<tic location='9'>September</tic>
<tic location='10'>October</tic>
<tic location='11'>November</tic>
<tic location='12'>December</tic>
<tic location='12'>December</tic>
</tics>
```

Note that tic locations are completely under your control and do not even have to be at regular interevals on the axis if that better suits your needs.

8.4 Color Selection

The default colors are a white background (xfffff) with black (x000000) forground, gridlines, and curve.

- Background color is an attribute of the gnuplot tag (see "Authoring Dynamically Generated Plots" section 8). This controls the color of the plot image. The default is white (xfffff).
- Foreground color is an attribute of the gnuplot tag (see "Authoring Dynamically Generated Plots" section 8). This controls the color of the border.
- Gridline color is an attribute of the axis tag (see "Plot Axes Details" section 8.3).
- Curve color is an attribute of the curve tag (see "Specifying Curves to Plot" section 8.1). This is the color of the curve function or data points. Different curves can be given different colors.

9 Authoring Function Plot Response Problems

9.1 Introduction

Creating a **Function Plot Response** problem involves several steps. This section introduces the major settings and subsequent sections cover other details.

"Label x-axis" and "Label y-axis" - Enter the label and/or units for the axes on the graph. Leaving them blank will result in no axis labels.

"Minimum x-value", "Maximum x-value", "Minimum y-value", and "Maximum y-value" - Entering values here will set the value of the graph at the left, right, bottom, and top edges (respectively). Default is -10, 10, -10, and 10 respectively.

"x-axis visible" and "y-axis visible" - This allows for each axis to be turned on or off.

"Grid visible" - This determines whether or not the grid is on the graph.

"Background plot(s) for answer" - This is a green curve the computer will display once the correct answer has been submitted. It is static, and can be given as a piecewise function. Since some problems will have multiple correct answers, this necessarily will only be a possible answer. Only the left hand side of the equation is necessary. For example, entering x + 2will display the line y = x + 2. The syntax must be syntax recognized by GeoGebra. To test syntax for Geogebra directly, visit http://www.geogebra.org/webstart/geogebra.html.

The tag should include the following additional subsections

- Response Elements
- Rule Set

9.2 Elements

Which Elements you use depends on the type of problem you want to make.

- Background Plot This places a static curve on the graph of your choosing. It can be labeled, moveable or fixed, and any color desired. Only the right hand side of the function you want displayed is necessary. For example, entering x + 2 will display the line y = x + 2. The syntax must be syntax recognized by GeoGebra. To test syntax for Geogebra directly, visit http://www.geogebra.org/webstart/geogebra.html.
- Spline At least one spline is necessary for a graph problem. These splines are what will be adjusted and analyzed to solve the problem.
- Object This places a point in the applet. Generally intended to be used with Vectors to create problems involving Free-Body Diagrams or any other points that vectors (or arrows) connect to and from.
- Vector This creates a vector (or arrow) in the applet. Generally intended to be used with Objects to create problems involving Free-Body Diagrams or to establish connections between Objects.

Splines

"Index" - This is the label assigned to the spline. In general, it's simplest just to label them A, B, C etc.

"Order" - This determines the number of Control Points on the spline. For example, selecting '3' means there will be 3 points on the spline that can be moved, as well as 3 points off the spline that will control the slope.

"Initial x-value" and "Initial y-value" - These values determine where the left most Control Point will be.

"Scale x" - This determines the right most location of the Control Points (on the spline). To figure out where this point will be, add 'Initial x-value' to 'Scale x'.

"Scale y" - This determines the distance (in the y-direction) between the Control Points on the spline, and the ones that control the slope.

Vectors

- "Label on Plot" Determines the name of the vector, as well as the name that will be visible in the problem. This value MUST be capitalized and cannot include spaces or most symbols. To be safe, stick with letters and numbers.
- "Tail x", "Tail y", "Tip x", and "Tip y" Determines where the vector's tail and tip will be placed in the applet when the problem is first loaded. Vectors are moveable by the students, and will not revert to these values after the student has submitted an answer.

Objects

- "Label on Plot" Determines the name of the object, as well as the name that will be visible in the problem. This value MUST be capitalized and cannot include spaces or most symbols. To be safe, stick with letters and numbers.
- "x" and "y" Determines where the object will be placed in the applet. The object is not moveable by the students, so whatever value is chosen here is fixed.

Background Plots

"Function" - Enter the function here. An equals sign is not necessary. Just give the right hand side of the function. LON-CAPA variables are usable as well to allow individualized problems for each student. The syntax must be syntax recognized by GeoGebra. To test syntax for Geogebra directly, visit http://www.geogebra.org/webstart/geogebra.html .

"Initial x-value" and "Final x-value" - The function does not need to span the entire graph. It is possible to create a piecewise function by defining the x-values over which each function is to be shown.

"Label on Plot" - To label the background function (for example, as "parabola"), enter it here.

"Color" - To change the color of the background function, enter the hex code for that color here. The default is 000000 (black). It is recommended to choose a color other than green, since it is easily confused with being the answer.

9.3 Rules

This is where the rules are defined. These rules will determine whether or not an entered answer is correct or not. If there are no rules, any answer will be deemed correct. If there is more than one rule, when an answer is submitted, the server will analyze them in order until one of them is broken (of course, if it's a correct answer, it will go through all of them and return a green box). In such an event, any subsequent rules will be ignored. If conditional hints related to these rules are added, only the first broken rule's hint will be shown, even if all rules are broken.

• "Graph Rule" - Used to evaluate graph problems.

- "Vector Rule" Used to test whether vectors are in the right place, pointed in the right direction, and have the correct length.
- "Vector Sum Rule" Used to test the sum of a set of vectors.
- "Custom Rule" Used to create rules that the other rules can't do. (Advanced)

Graph Rule

Overview - This box is used to create a rule that determines whether or not a submitted graph is correct. In general, it takes the form of testing the function, its integral, or its first or second derivative over a given set of x-values. The test can be to see if it equals, is greater than, or less than a specified value. Anywhere a number is needed, a variable can also be used. (Skip to the bottom for examples of rules.)

- "Index/Name" This is an internal label for the rule. Something must be entered here, and it must be different for each rule. This same value will be used to add a conditional hint.
- "Function" This determines what the server will be testing. For instance, choose 'First derivative' causes the server to evaluate the derivative of the entered answer over the given domain.
- "Initial x-value" and "Initial x-value label" A value must be entered for one of these. Either choose a numerical value for x (the first option), or choose the beginning of the submitted answer, the end, or a previously chosen named point (see below).
- "Final x-value" and "Final x-value label" This determines the end of the domain over which the rule examines. To test only a single point (the initial value), leave these blank. If a label is entered, such as 'positive', the point at which the rule fails will be given this special label. This label can then be used in subsequent rules as an 'Initial x-value label'.
- "Minimum length for range" This tests that the difference between the initial and final x-values are at least a certain length apart. This is only useful if there is at least one label.
- "Maximum length for range" This tests that the difference between the initial and final x-values are at most a certain length apart. This is only useful if there is at least one label.
- "Relationship" The heart of the rule. This choice determines whether the chosen 'Function' is greater than, less than, equal to, etc. a certain 'Value'.
- "Value" Enter the number you wish to compare to. It is also possible to choose 'not defined', in the event the answer should not have a value for the given domain. Within the value argument, the function itself can be evaluated using &fpr_f(), its derivative using &fpr_dfdx(), and its second derivative using &fpr_d2fdx2(). This allows for a

comparison of two points on the graph. The value of a previously defined label can be retrieved using the function &fpr_val(), e.g., &fpr_val('positive'). Previous defined values from script blocks can also be retrieved as normal variables, e.g., \$x.

• "Percent error" - This allows for a margin of error in the y-direction. For instance, if the rule requires that the derivative be equal to 5, the server will accept values close enough to 5 that are within the percent error defined here. Note: Choosing 10% would not mean that the answer is correct as long as it is within the range 4.5-5.5. Instead, the percent corresponds to the total size of the graph. For the function itself, the 'percent error' is multiplied by the ymax-ymin; for the first derivative, it's multiplied by (ymaxymin)/(xmax-xmin); for the second derivative, it's multiplied by (ymax-ymin)/(xmaxxmin)²; and for the integral, it's multiplied by (ymax-ymin)*(xmax-xmin).

The figure below shows some examples of rules.

1. Checks that the derivative at x = 3 is negative.

- 2. Checks that the second derivative at x =time1 is 0.
- 3. Checks that the value of the function > 7 from "Start of Graph" to x = 5.
- 4. Checks that the function is 0 from x = 0 until the function is no longer 0, labeling this new point 'notzero'.
- 5. Checks that the first derivative is positive between the point 'notzero' and the end of the graph.
- 6. Checks to see that the value of the function at x = 4 is the same as the value of the function at \$time2. The Value here is &fpr_f(\$time2).
- 7. Checks that the value of the function at point 'notzero' is equal to the value of the function at x = time3. The Value here is &fpr_f(&fpr_val('notzero')).

Vector Rule

- "Index/Name" This is an internal label for the rule. Something must be entered here, and it must be different for each rule. This same value will be used to add a conditional hint.
- "Vector" The name of one of the vectors in the list of Elements above. Specifically, the one you want to test.
- "Attached to object" Enter the object(s) this vector should be attached to. For more than one object, separate them by commas. If the vector should not be attached to any object, leave this blank. In this case, an object is considered attached if its tail OR its tip is in the vicinity of the object.
- "Not attached to object" Enter the object(s) that this vector should be not be near. For more than one object, separate them by commas. Particularly useful for distractor vectors.
- "Tail/Tip (not) attached to object" The same as the previous two statements, but specific to only the Tail/Tip of the vector.
- "Length" How long the vector should be.
- "Absolute error length" How accurate the length must be to get the answer correct.
- "Angle" What direction should the vector point. All values are measured in degrees, counterclockwise starting at the positive x-axis. Values must be $0 \le \theta < 360$
- "Absolute error angle" How accurate the angle must be to get the answer correct.

Vector Sum Rule

- "Index/Name" This is an internal label for the rule. Something must be entered here, and it must be different for each rule. This same value will be used to add a conditional hint.
- "Comma-spearated list of vectors" List all of the vectors that should be added up to be tested.
- "Length" How long the sum of these vectors should be.
- "Absolute error length" How accurate the length must be to get the answer correct.
- "Angle" What direction should the sum of these vectors point. All values are measured in degrees, counterclockwise starting at the positive x-axis. Values must be $0 \le \theta < 360$
- "Absolute error angle" How accurate the angle must be to get the answer correct.

Custom Rule

Used to create rules that aren't options using the other rules. The coding is done in Perl and follows Perl syntax. Any variable written inside this rule will be recognized as normal and any evaluation function can be used as well.

Available evaluation functions:

```
1. &fpr_val("label")
```

- 2. $& fpr_f(x)$
- 3. $& fpr_dfdx(x)$
- 4. $& fpr_d2fdx2(\$x)$
- 5. (\$xs,\$xe,\$ys,\$ye)=&fpr_vectorcoords("Name")
- 6. (\$x,\$y)=&fpr_objectcoords("Name")
- 7. &fpr_vectorlength("Name")
- 8. &fpr_vectorangle("Name")

Returning 1 is correct, while returning 0 is incorrect. Example comparing the lengths of two vectors:

```
if (&fpr_vectorlength("Normal") < &fpr_vectorlength("Gravity"))
{return 1;}
else
{return 0;}</pre>
```

10 Using Libraries

Library (.library) files can hold an assortment of content. Library content is loaded into a problem statement by using an <import> tag. For more information about the import tag, see section 15.8.

10.1 Authoring Library Files

A LON-CAPA .library file can contain just a script block, or just response items, or both. A LON-CAPA problem can import as many published library files as desired. A .library file always starts with a library> tag, and always ends with a </library> tag.

Storing entire scripts

Entire scripts can be stored in a library file. The entire script can then be imported into a problem file.

Library file:

```
<library>
```

```
<script type="loncapa/perl">
    @alpha=('A','B','C','D',);
    $seed=&random(1,1000000,1);
    @alpha=&random_permutation($seed,@alpha); #scramble order
    $letter = $alpha[0]; #select first element
    </script>
</library>
```

Problem file:

```
<problem>
<import id="15">randomletter.library</import>
<startouttext />The random letter is $letter.<endouttext />
<!-- other problem tags could go here -->
</problem>
```

Storing a portion of a script

A portion of a script, such as a large data array can be stored in a library file.

```
Library file:
```

```
<library>
<script type="loncapa/perl">
@alpha=('A','B','C','D',);
$seed=&random(1,1000000,1);
@alpha=&random_permutation($seed,@alpha); #scramble order
</script>
</library>
```

Problem file: (note the <script> tag is repeated and other script calculations can be done using variables from the library file.)

Storing a subroutine

Another use of a .library file is to define a subroutine which you plan to call in a number of instances, e.g., (see notes below about browsing libraries in the repository to see the contents of this subroutine)

/res/msu/raeburn/cleaneq.library

Here is some example XML problem code which makes a call to the &cleaneq() routine defined in the library file, passing some arguments: \$eq,'x','y','z' in the call to the routine.

```
<problem>
<import id="15">/res/msu/raeburn/cleaneq.library</import>
<script type="loncapa/perl">
    $eq = "1x + 0y +-7z --3";
    $eq2 = &cleaneq($eq,'x','y','z');
</script>
<startouttext />Here is an example equation:<br />
Without cleaneq: $eq<br />
With cleaneq: $eq2<endouttext />
</problem>
```

Assigning random problems using libraries Libraries can be used to store alternative parts of problems which are selected with the <randomlist> tag. The .library file hold the all content that would normally appear inside the <part> tag.

```
<part id="11">
  <randomlist show="1">
    <import id="12">sample1.library</import>
    <import id="13">sample2.library</import>
    <import id="14">sample3.library</import>
    </randomlist>
```

```
</part>
<part id="15">
<part id="15">
<part id="15">

<import id="16">sample4.library</import>

<import id="17">sample5.library</import>

<import id="18">sample6.library</import>
</part>
</part>
```

Note: when using <randomlist> as shown above, all students will work every part of the problem, but the actual problem statements will be different. Another option is to wrap multiple <part> tags but then not all students will work all parts unless the value of 'show' equals the total parts wrapped. For more information see section 15.8.

Viewing the text contents of a library script block

If you click on a .library file when browsing the shared content repository, and the .library file contains just a script block, then nothing will be displayed in the pop-up window.

The code is viewable if the author has enabled access to the source XML when publishing a .library item that is pure script block. If that is done, then when a user checks the "Source Available" checkbox when browsing the shared content pool, a link will be displayed for items with available source code. Clicking the "Source Code" link for any such items will open a pop-up which displays the content of the library file. It is good practice to enable access to the source code when publishing any library that will be shared. Otherwise, users cannot see it.

Viewing variables from a library script during testing

When viewing a problem in the problem testing mode of Authoring Space, you will see a separate Script Vars link at the bottom of the testing area for each script block (either a block included directly within the file, or a block included within a library file imported into a problem). By clicking the respective link, you can view variable values from the respective script.

Accessing submissions from a problem part loaded from a library

When *response items (e.g., *response is a wildcard such as option responce, stringresponse, numerical response, etc.) are defined in a .library file, this results in an extra id item in the identifier required in &EXT() functions, e.g., if a problem contains two parts with ids of a and b respectively, and the id of the <import> for the .library is 15, and the *response items have ids of 11 and 12 respectively, the most recent submissions could be retrieved with the following &EXT() calls.

```
&EXT("user.resource.resource.a.15_11.submission");
&EXT("user.resource.resource.b.15_12.submission");
```

11 Authoring Adaptive/Conditional Hints

Hints are placed within <hintgroup></hintgroup> tags. The first part of the hint is the condition, which includes a specification of the foil(s) and foil answer(s) required to trigger the hint. The answers specified in the hint condition are compared with the user's submission, and if the condition is met, the hint action included in the conditional hint block will be executed (for example this could be the display of a block of text). You can set multiple hint conditions for a particular problem. Hint condition name in the "on" parameter. When a hint condition evaluates to true, the corresponding hint action is triggered. Besides providing hint actions within <hintpart on="NAME"></hintpart> tags for each named (NAME) hint condition, a hint can be designated for display if none of the conditional hints evaluate to true. The default hint is not displayed if the conditions were met for any of the conditional hints. The default hint action is included between <hintpart on="default"></hintpart></hintpart></hintpart> tags. There are five types of hint condition:

- Formula Hint condition
- Numerical Hint condition
- Option Response Hint condition
- Radiobutton Hint condition
- String Hint condition

The syntax used to describe the foil(s) and the foil answer(s) differ for the five types:

1. Formula Hint condition

The formulahint tag takes three parameters: answer, name, and samples. The "name" is the unique name given to the hint condition. The formula answer for which you wish to provide conditional is included in the answer parameter. The samples parameter includes the points (or range of points) over which sampling of the student's submitted answer and the formula included in the formula hint answer parameter are to be compared. The syntax is the same as used to specify sampling points in the samples parameter of the formula reponse tag itself. The formula submitted by the student is evaluated at the sample points for the hint and the calculated values are compared with the corresponding values determined by evaluating the "hint" answer at the same sampling points. A close correspondence between the two sets of values will trigger the hint action specified in the <hr/>hintpart> tag.

```
<problem>
<script type="loncapa/perl" ># Enter computations here
$x1 = random(2,4,1);
$y1 = random(3,7,1);
```

```
x^2 = random(x_1+1,9,1);
 y_2 = random(y_1+1, 15, 1);
 m = "(y_2-y_1)/(x_2-x_1)";
 b = "y_1-m*x_1";
 $answer = "$m*x+$b";
 answer = s/+-/-/g;
 answer = s/-+/-/g;
 $inverted = "($x2-$x1)/($y2-$y1)";
 $wrongans = "$inverted*x";
 \ symmetry s = s/+-/-/g;
 \ symbol{wrongans} = s/-+/-/g;
</script>
<startouttext /> What is the equation of the line
which passess through (x1,y1) and (x2,y2)? y = <endouttext />
<formularesponse samples="xQ-5:5#11" id="11" answer="$answer">
 <textline size="25" />
  <hintgroup>
   <formulahint samples="x0-5:5#11" answer="$wrongans" name="inversegrad">
   </formulahint>
   <hintpart on="inversegrad">
    <startouttext />You have inverted the slope in the question. Slope is
(y^2-y^1)/(x^2 - x^1) you have the slope as (x^2-x^1)/(y^2-y^1).<endouttext />
   </hintpart>
  </hintgroup>
 </formularesponse>
</problem>
```

2. Numerical Response condition

The numericaliant tag takes four parameters: answer, name, unit and format. The "name" is the unique name given to the hint condition. The numerical answer for which you wish to provide conditional is included in the answer parameter. Student submission of that answer in combination with the "unit" parameter in the hint condition will trigger the hint action specified in the <hintpart> tag.

```
<problem> <startouttext /> A car travels 10 km in 10 min.
What is the speed of the car?<endouttext />
        <numericalresponse format="1f" unit="km/hr" answer="60">
        <responseparam description="Numerical Tolerance" default="2%"
        type="tolerance" name="tol" />
        <textline />
        <hintgroup>
        <numericalhint format="1f" unit="km/min" answer="100" name="speed">
```
```
<responseparam description="Numerical Tolerance" type="tolerance"
default="2%" name="tol" />
</numericalhin >
<hintpart on="speed">
<startouttext />You multiplied the distance by the time. Remember
speed = distance/time<endouttext />
</hintpart>
</hintgroup>
</numericalresponse>
</problem>
```

3. Option Response Hint condition

There are two types of option response hint conditions: one for standalone foils and one for concept groups. In both cases the option hint tag includes two parameters: answer and name for standalone foils, and concept and name for foils grouped together in a concept group. For the answer parameter, the names and submitted values for each of the foils that are being included in the hint condition are provided in a hash, i.e., in the format: ('Foil1'=>'True', 'Foil2'=>'False'). In the case of a conditional hint for a concept group, the format of the concept parameter is also a hash that links the name of each concept group included in the hint condition to either 'correct' or 'incorrect' - e.g., <optionhint concept="('buoyancy'=>'correct','density'=>'correct')" name="fluids" /> If 'correct' is specified for a named concept then when the conditional hint is evaluated answers for each of the foils selected by a student must be correct for the hint action to be triggered. If anything other than 'correct' is provided in the concept hash in the option int tag then then students answers will be compared with the set answers for the foils in the concept group and as long as at least one answer is incorrect (i.e., the concept group was not correctly answered) then the corresponding hint action will be triggered.

(a) optionresponse

```
<problem>
<startouttext />For each of the following rock types, indicate
whether or not the rock is a volcanic rock.<endouttext />
<optionresponse max="10" randomize="yes">
<foilgroup options="('Yes','No')" >
<foil location="random" value="No" name="schist">
<startouttext />Schist<endouttext />
</foil>

       magma.<endouttext />
   </foil>
   <foil name="nonvolcanic" value="Transform">
      <startouttext />No volcanic activity.<endouttext />
   </foil>
 </conceptgroup>
</foilgroup>
```

```
<hintgroup>
     <optionhint concept="('earthquakes' => 'incorrect')"
       name="quakes" />
     <optionhint concept="('volcanism' => 'incorrect')"
       name="volcactivity" />
     <optionhint concept="('topography' => 'incorrect')"
       name="relief" />
     <hintpart on="volcanism">
       <startouttext />Volcanism requires a source of magma.
        Magma can be generated by either a depression in the solidus
        caused by an influx of volatiles, or by decompression melting.
        Magma rich in volatiles tends to cause explosive volcanism.
        <endouttext />
     </hintpart>
     <hintpart on="quakes">
       <startouttext />Earthquakes require brittle failure, so there
        is a correlation between the depth of earthquake foci and the
        geotherm. The geotherm is depressed in subduction zones, and
        elevated at mid-ocean ridges.<endouttext />
     </hintpart>
     <hintpart on="relief">
       <startouttext />On a broad scale topography is an expression
        of density variation, as embodied in the concept of isostasy.
        Density variation in the earth is a function of temperature and
        composition. Cold oceanic crust entering a subduction zone is
        dense, whereas as magma is buoyant and of lower density.
        <br /><br /><endouttext />
     </hintpart>
    <hintpart on="default">
    <startouttext />The characteristics of plate boundaries are
       described on page 52 of the textbook. <endouttext />
    </hintpart>
   </hintgroup>
</optionresponse>
</problem>
```

4. Radiobutton Hint condition

The radiobutton hint tag takes two parameters: answer and name. The name is the name of the hint condition, and the answer is an array. The first element of the array will be 'foil'; the remaining elements are the names of the foils that you require to have been checked by the student for the hint to be displayed. For example, if you create a radiobutton response problem with six foils named: granite, gabbro, gneiss, shale, sandstone and schist, and you want your hint named: igneous to be displayed when either granite or basalt had been checked your radiobutton hint would be as follows:

```
<radiobuttonhint answer="('foil','granite','gabbro')"
name="igneous"></radiobuttonhint>
```

In order to trigger display of this hint you also need to create a <hintpart></hintpart> block that will include a textblock that contains the text of the actual hint.

```
<hintpart on="igneous">
  <startouttext />This type of rock is composed of interlocking
  crystals, a characteristic of igneous rocks.<endouttext />
  </hintpart>
```

The complete radiobutton response would look as follows:

```
<problem>
 <startouttext />
Which of the following is a sedimentary rock?
 <endouttext />
 <radiobuttonresponse max="3" randomize="yes">
   <foilgroup>
     <foil location="random" value="false" name="granite">
   <startouttext />
     Granite
    <endouttext />
   </foil>
  <foil location="random" value="false" name="gabbro">
   <startouttext />
    Gabbro
    <endouttext />
   </foil>
   <foil location="random" value="false" name="schist">
    <startouttext />
     Schist
    <endouttext />
   </foil>
   <foil location="random" value="false" name="gneiss">
   <startouttext />
     Gneiss
   <endouttext />
   </foil>
```

```
<foil location="random" value="true" name="shale">
    <startouttext />
     Shale
    <endouttext />
   </foil>
      <foil location="random" value="true" name="sandstone">
    <startouttext />
     Sandstone
    <endouttext />
   </foil>
  </foilgroup>
  <hintgroup>
   <radiobuttonhint answer="('foil', 'granite', 'gabbro')"
name="igneous" ></radiobuttonhint>
   <radiobuttonhint answer="('foil','gneiss','schist')"
name="metamorphic"></radiobuttonhint>
   <hintpart on="igneous">
    <startouttext />This type of rock is composed of interlocking
      crystals, a characteristic of igneous rocks.<br /><br /><endouttext />
   </hintpart>
   <hintpart on="metamorphic">
    <startouttext />This type of rock is composed of oriented crystals, a
characteristic of foliated metamorphic rocks.<endouttext />
   </hintpart>
  </hintgroup>
 </radiobuttonresponse>
</problem>
```

5. String Hint condition

The radiobutton hint tag takes two parameters: answer and name. The name is the name of the hint condition, and the answer is a text string. The type parameter allows you to choose between case sensitive, case insensitive, and case insensitive in any order. A simple example is shown below.

```
<problem>
<startouttext />Which US state has Lansing as its capital?<endouttext />
<stringresponse answer="Michigan" type="ci">
<textline size="20" />
<hintgroup>
<stringhint answer="wisconsin" type="cs" name="wisc">

</hintpart>
<hintpart on="default">
<startouttext />The state you are looking for is also known as the
'Great Lakes State'<endouttext />
</hintpart>
</hintgroup>
</stringresponse>
</problem>
```

12 Publishing Your Resources

In order to make the content you've created available for use in courses, you must publish your content. LON-CAPA provides an easy interface for publishing your content pages, problem resources, and sequences. You can specify title, author information, keywords, and other metadata. LON-CAPA uses this metadata for many things, and it's important to fill the metadata out as accurately as possible.

12.1 What is Metadata?

Metadata is *data about data*. Metadata can often be thought of as a label on some bit of information that can be useful to people or computer programs trying to use the data. Without metadata, the person or computer trying to use the original information would have to guess what the original data is about.

When resources are published at least title, subject and keywords should be provided so that the resource could be found easily.

For example, if you create a problem and neglect to say in the title or subject of the problem what it is about, then a human who wants to use that problem would have to read the problem itself to see what it was about. This is much more difficult than just reading a title. A computer trying to do the same thing would be out of luck; it is too stupid to understand the problem statement at all.

Another example of metadata is the <title> tag of a web page, which usually shows up in the title bar of the browser. That is information about the web page itself and is not actually part of the web page. People use the title information when they bookmark a page. Search engines use it as a clue about the content of the web page.

12.2 Publishing a Resource

To publish a resource, log in and choose your Author role. You should see something like the resource listing of the figure 4. Use the **Actions** dropdown to select **Publish** for the resource you wish to publish. You will get a metadata screen that should look something like the "Publishing Metadata Screen" figure. Fill out the form. If you are creating resources that may be used in several courses, you should talk with the other authors and establish some sort of standard title and subject scheme in advance.

Language is the language the problem is written in. Publisher/Owner is the LON-CAPA user who owns the problem.

Keywords and Abstract are more information about the problem.

The **Keywords** are words that are strongly connected to your problem; for instance a physics problem about a pulley might include "pulley" as a key word. LON-CAPA pulls out words used in the text of the resource for you so you can just click on their check boxes to make them keywords. Additional keywords allows you to add any keyword to your problem that are not actually in the problem. For instance, on that same problem a physicist might add the keyword "statics", even though it doesn't appear in the original problem, because Physics uses that as a classification of problem type. Additional Keywords are also useful when publishing graphics.

You need to set the copyright and distribution permissions in the

COPYRIGHT/DISTRIBUTION drop-down. This setting controls who is allowed to use your resource as follows:

- System Wide can be used for any courses system wide is the default. The content can be used for any course within the network, regardless of the domain. Instructors all over the world can find your content and use it in their courses. Once an instructor has selected a resource, the students in the course can have access to it.
- Domain Limited to courses in the domain published means that only courses running in the same domain as you can use your content.
- **Private visible to author only** is not supported anymore. Use *Customized right* of use instead.
- Public no authentication required means anyone can find and use the resource even without being logged in to the system.
- Customized right of use means that access to the resource is controlled by a separate Custom Rights file. This file needs to be specified during publication. You can edit a Custom Rights file in your author space, and need to publish it like any other file. Any number of your resource can point at the same Custom Rights file if you want to change access rights for all of them, you just need to change and re-publish this one file.

Not all of these choices may be visible, depending on the nature of the resource.

Now when you click **Finalize Publication**, your resource will be published and usable (unless you set the distribution to "private").

Title:

Finalize Publication

If you're following this as a tutorial, publish your resources so we can use them in the next section.

13 Printing Your Resources

13.1 Printing from Authoring Space

To print a resource, do the following:

- 1. The icon will only be accessible when you are looking at one of your resources for your course.
- 2. Click to access the Print Helper, which will help you create a PDF document.

The Print helper will guide you through the process of preparing a PDF document of the resource. If you see error message when trying to prepare a PDF file, then you will need to contact the author of the problem which contains that printing error.

Printing involves a translation of your XML file into LaTeX and from there to PDF. Some of the XML tags have a set of special print options, see 13.3. Sometimes translations require special considerations, see 13.4.

13.2 Printing a Subdirectory of Problems

Authors or co-authors will typically choose to organize their authoring spaces into subdirectories. To generate a PDF containing all problems in an entire directory or sub-directory, follow the steps below:

- 1. First, select one of the problems to view in the sub-directory to be printed.
- 2. Click Print in the Functions menu if using the Inline menu, or the PRT buttom on the Remote Control.
- 3. Select the option to print 'Selected Problems' from current subdirectory.'
- 4. Optionally, choose to print with Answers. You can choose to print with either the default two column output or with one column.
- 5. Click the Next button.
- 6. On the next screen, select which problems you want to print by either clicking on one of the Select buttons or individually checking which problems you want to select.
- 7. Click the Next button.
- 8. As long as there were no errors in any of the problems, you should now see a link to a PDF file that you can download and view.

If an error occurs with just one of the problems then printing of all selected problems in the sub-directory will fail. LON-CAPA will make a guess at which problem(s) had errors. You will need to troubleshoot and fix those problems before the entire directory can be printed. Information about common print errors is available at 13.4.

13.3 Tips for Improving Print Output

Here you can find some useful tips how to make your printing output looking prettier. Print output oriented attributes of standard HTML/LON CAPA tags

- 13.3.1 <h1>-<hN> TeXsize attribute
- 13.3.1 <basefont> TeXsize attribute
- 13.3.1 TeXsize attribute
- 13.3.2 <hr> TeXwidth attribute
- 13.3.2 TeXwidth attribute
- 13.3.3 TeXDropEmptyColumns attribute
- 13.3.2 TeXwidth attribute
- 13.3.2 **TeXwidth** attribute
- 13.3.4 TeXwidth attribute
- 13.3.4 TeXheight attribute
- - texwrap (the default) uses the texwrap environment to attemp to get text to wrap around the picture. This requires either a "left" or "right" alignment, and works well in most cases.
 - parpic uses the picins package \parpic to attempt to get text to wrap around the image. This method places the remainder of the text of the paragraph containing the picture to the left or right of the picture. This scheme has two drawbacks: If the remainder of the paragraph text is insufficient to fill the area to the side of the image, the text from the following paragraph will run through the image, parpic also seems to not do a good job of honoring the end of the page, and images can spill below the page footers generated by Lon-CAPA.

13.3.1 TeXsize Attribute

 ${\bf TeXsize}$ attribute in <h1>-<hN>,<basefont>, and tags declares the size of LaTeX fonts used in printing.

Possible values of **TeXsize** attribute:

tiny	smallest	
scriptsize	very small	
footnotesize	smaller	
small	small	
normalsize	normal	
large	large	
Large	larger	
LARGE	even larger	
huge	still larger	
Huge	largest	

Note, that all parameters coincide with standard LaTeX commands for changing font size though you do not escape them.

Examples:

```
<basefont size="4" TeXsize="Large" /><font color="#FFFFF" TeXsize="small"><h1 align="center" TeXsize="Huge">
```

13.3.2 TeXwidth Attribute

TeXwidth attribute allows you to specify the width of

- the table in tag
- the table cell in or tags
- the length of the line in <hr> tag

You can use the following units:

mm	
cm	=10 mm
in	=25.4 mm
pt	=0.35 mm
\mathbf{pc}	=4.22 mm

Examples:

<hr TeXwidth="2 cm">

13.3.3 TeXDropEmptyColumns Attribute

TeXDropEmptyColumns attribute allows you to supress printing of empty columns in table. This option is useful when you have deal with big tables (very often nested) with a lot of empty columns. Situation is typical in chemistry where tables are used for visualization of chemical reactions.

Example:

13.3.4 Image TeX Attributes

- Image Url contains the URL of the image to be inserted in the problem. You may enter a URL or click "Select" to choose an image that has already been uploaded to your authoring space, or click "Search"
- Description contains a textual description of the image. If the image cannot be rendered by the target browser, this description is displayed instead.
- width (pixel) allows you to set the width of the image, in pixels, as it will be displayed in a web browser.
- height (pixel) allows you to set the height of the image, in pixels, as it will be displayed in a web browser.
- TeXwidth (mm) Allows you to set the width of the image, in mm, as it will be rendered into the LATEX document used to print the problem.
- TeXheight (mm) Allows you to set the height of the image, in mm, as it will be rendered into the LAT_EX document used to print the problem.
- TeXwrap Allows you to select how the LATEX document will attempt to wrap text around a horizontally aligned image (See Alignment below).
 - parbox \newline and \parbox will be used to place the image. This method ensures that text will not be wrapped on top of the image, however very little text will appear next to the image itself.
 - parpic The picins package \parpic command will be used to place the image. This will wrap the remainder of the paragraph containing the picture around the image. If, however, there is insufficient text to fill the space to the left or right of the image, the next paragraph may be wrapped on top of the image. In addition, \parpic does not always honor the end of the page, causing the image to extend below the page footer.
- Alignment Specifies the alignment of the image relative to the enclosing text paragraph:
 - bottom The image will be aligned so that its bottom will be at the baseline of the surrounding text.

- middle The image will be aligned so that its center-line will be at the baseline of the surrounding text.
- top The image will be aligned so that its top will be at the baseline of the surrounding text.
- left The image will be placed so that it is at the left of the surrounding text. The surrounding text will fill in the region to the right of the image.
- right The image will be placed so that it is at the right of the surrounding text. The surrounding text will fill in the region to the left of the image.

13.3.5 TeX Type Attribute

TeXtype attribute is responsible for the definition of the type of LaTeX list environment used during printing of available options. Possible values of this attribute:

TeXtype attribute is responsible for the definition of the type of LaTeX list environment used during printing of available options. Possible values of this attribute:

value	example of list
1	[1.] First Item
	[2.] Second Item
	[3.] Third Item
A	[A.] First Item
	[B.] Second Item
	[C.] Third Item
a	[a.] First Item
	[b.] Second Item
	[c.] Third Item
i	[i.] First Item
	[ii.] Second Item
	[iii.] Third Item

Examples:

<radiobuttonresponse TeXtype="1"> <radiobuttonresponse TeXtype="A">

13.3.6 TeX Itemgroup Width Attribute

TeXitemgroupwidth attribute allows you to specify the width of table with items for matching. The value of this attribute defines the width in percents with respect to text line width.

<matchresponse TeXitemgroupwidth="40%">

13.3.7 TeX Layout Attribute

TeXlayout attribute governs the way how available options are displayed when printed either vertically (attribute value - "vertical") or horizontally (attribute value - "horizontal). Examples:

Examples.

<optionresponse TeXlayout="horizontal">
<optionresponse TeXlayout="vertical">

13.4 Troubleshooting PDF Errors

When you print a LON-CAPA resource, the XML of your resource is translated into LaTeX. The LaTeX is then processed and turned into a PDF document which can be displayed with your browser's Acrobat plugin and subsequently printed.

There are several problems that crop up both due to limitations in the XML to LaTeX translation and due to differences in the model used by web browsers to render HTML and LaTeX to compose print pages. This document provides information about some of these problems and, where possible, solutions, and tricks to work around them. If you have a printing trick or a problem and would like to report it, please go to http://bugs.lon-capa.org and register a bug report.

General information about printing within LonCAPA is also available in section 13.1. Some types of problems that may occur include:

The print rendition of some Perl functions looks ugly

In particular these functions are:

- & prettyprint
- &dollarformat
- &xmlparse
- & chemparse

To make these two functions work correctly within the print translator, it is necessary to wrap them within a <display> tag. For example:

```
If I had <display>&prettyprint(100,'$2f')</display>
```

Note that the <display> tags must be tightly wrapped around the function call or you will get a syntax error in web presentation mode. For additional information about cases where you must use <display>, see "Variables with tags don't print correctly" below.

Image placement and alignment and text wrapping is wrong

Unfortunately this is due to a large difference between the LaTeX and HTML page layout model. In HTML images are placed exactly where you ask them to be placed. In LaTeX,

images are considered *floats*, which LaTeX will place for you. Some of the common html tricks, using tables e.g. to control text wrapping around figures, will not always work in print mode; especially if the text is to the right side of the figure in the table.

The alignment choice affects whether or not the print rendering engine attempts to get text to wrap around the image. With align="right" or align="left", the print rendering engine attempts to use the *wrapfigure* environment to place text around the figure at the appropriate side. If a figure is in a table, then the print engine, by default, the print engine will use wrapfigure, set the alignment to "right" unless you override it. Otherwise, the default alignment is "bottom" as it is for html, and no wrapping will occur.

\parpic style wrapping is also available by specifying TeXwrap="parpic" in the tag. In some limited casese this gives a better result.

Other print specific $\langle img \rangle$ tag attributes are available (see section 13.3).

Variables with tags don't print correctly

If a variable contains XML, in general it is necessary to force the XML parser to make a pass over the contents of the contents of the variable prior to rendering the section of the resource that contains that substitution. When output, those variables must be bracketed inside of <display> </display> tags. For example:

```
<problem>
<script type="loncapa/perl">
$a = &xmlparse('<br />');
</script>
<startouttext />
This is a break <display>$a</display> and then some more text
<endouttext />
</problem>
```

Without the xmlparse call and the display tag bracketing the variable, this problem will display on the web just fine, but print incorrectly.

14 Authoring Maps: Sequences and Pages

In order to create a useful course, we need to arrange our raw materials so that students can use them.

14.1 Authoring Sequences

A sequence is a series of resources that can be navigated using the **NAV** remote control button, or by using the arrow keys on the remote control.

To create a Sequence resource, create a new resource as described in the 'Authoring Content in LON-CAPA' section (5). This is a "sequence" resource so the URL must end in ".sequence". After you enter in the URL ending in ".sequence", you should see a screen as in figure 23. You can use either the advanced editor or the simplified editor.

Figure 23: Map Editor Selection

Figure 24: Simple Map Editor

14.2 Authoring a Simple .sequence With The Simple Editor

After creating a new .sequence resource and getting the editor selection prompt (as in the "Simple Map Editor" figure), click the **Simple Edit** button to get to the simple map editor, which appears in the figure.

The Simple Editor can create .sequences and .pages which are linear, which means they have no branches or conditions.

On the right side of the simple editor is the **Target**, which represents the map you are currently building. On the left side is the **Import** area, which represents a work area you can use for your convenience to load and manipulate resources you may wish to include in your map. Using the three buttons in the middle of the screen, you can cut things out of the Target (top button), copy from the Target to the Import (middle button), and copy from the Import to the Target (bottom button).

You can do a Group Search and a Group Import on both sides of the screen. A Group Search allows you to run a search, then import selected results from that search either directly into your Map or into your Import space. Checkboxes will appear next to the results in the Group Search, and you can click the resources you wish to add to your map in the order that you want them added. After you select the resources, you will be presented with a screen that allows you to change their order. You will then be able to import the selected resources

Figure 25: Initial Map Editor

and work with them.

A Group Import works in a similar fashion, but allows you to use the LON-CAPA network browser to select your resources.

On the Import side, you can also browse for another Map, and load the resources used in that map into your Import workspace. You can also discard the selected resources, clear all the resources, and view the selected resources by using the buttons on the Import side of the screen.

Both list boxes support standard multi-select mechanisms as used in your OS.

14.3 Authoring a Simple .sequence With The Advanced Editor

After creating a new .sequence resource and getting the editor selection prompt (23), click the **Advanced Edit** button to get to the advanced map editor. You should see the initial map editor as shown in the "Initial Map Editor" figure. Note there are two windows: One is the workspace and one is a secondary window which will contain information as you add resources.

Click the **Start** box. You'll see what is shown in the "After clicking **Start** in the Map Constructor" figure. Click **Link Resource** in the secondary window then click on the **Finish** box. After that, click **Straighten**. You should see something looking like the "Straightened Map" figure. This creates a simple map that flows from beginning to end.

To insert a resource into the flow, click the black line with two arrows, seen between the **Start** and **Finish** boxes in the "Straightened Map" figure. In the secondary window, you will see something like the "Inserting a Resource" figure. Click **Insert Resource Into Link**. A new resource box will appear in the link. Click the resource, which will have the label **Res**.

Figure 26: After clicking **Start** in the Map Constructor

Figure 27: Straightened Map

Figure 28: Inserting a Resource

3. Click **Browse** and the **Network Directory Browser** will appear, as shown in the "Network Directory Browser" figure. Press the **SELECT** button that is next to the resource you want to place in the chosen resource box. Once you've done that, if you look back at the window that popped up when you clicked on **New Resource**, you'll see something like the "Resource Chosen" figure. You can type the **URL** and **Title** into the secondary window if you prefer, following the format you see when you've successfully browsed to a resource. After you click **Save Changes**, your changes will be set and the icons for the resource will appear in the **Res** box, as shown in figure 30. Click **Save Map** in the bar above your map to save the map.

Clicking on the left icon for a resource will open a new browser window with an informational page about that resource. Clicking on the right icon for a resource will open a new browser window and take you to the rendering of that resource.

- 4. Repeat steps two and three for as many resources as you'd like to bind together into one page. You can insert the new resources anywhere you'd like.
- 5. When you are done adding resources, click the **Save Map** link to save the map.

In addition to manually adding in resources, the Advanced Editor also has the ability to import resources in the same way that the Simple Editor can: From a LON-CAPA network browser window, from a Group Search, or from another Map.

The Advanced Editor has many more capabilities which you can explore.

14.4 Adding links and conditions

Any resource can potentially be linked to any other, making it possible to provide a non-linear learning experience. Once a few resources have been added to a sequence in the advanced editor, links can be added by simply clicking on a resource, using the "Link Resource" link, and clicking on another resource. The map display will update to take into account the new

SELECT	msu-prob05.pr	roblem (metadata)	23

Figure 29: Network Directory Browser

Figure 30: Resource Chosen

link. By default, all links out of a resource will be suggested to students switching to the next resource in the sequence, but it is possible to reduce the options with conditions.

A condition for a link can be added by clicking on a link near a resource (in a colored area) and typing the condition in the pop-up. Conditions are using the Perl syntax, and are evaluated as booleans. Three different outcomes are possible for a given condition:

- Recommendation if true: displays the link only if the condition is true
- Blocking this link if false: hides the link if the condition is false
- Blocking other links if true: hides the other links if the condition is true

The &EXT function is used to get user data. It takes 2 parameters: one to specify the problem part and requested data, and one to specify the sequence resource. Resources in the sequence have to be named before being used with &EXT. This is done by adding a mapalias parameter to the resource. To do that, click on a resource, click the *Set Parameters* link, change the value for the parameter_part_mapalias field, click on the *Set* checkbox, then click on the *Set* button.

Here is an example:

&EXT('user.resource.resource.0.tries','test') > 2

This condition will be true if the user has more than 2 tries for the problem with a mapalias parameter set to "test", in part 0 (which is the part id used when a problem has no part).

Here are some &EXT parameters that are particularly useful for advanced sequences:

- awarded: '' or a floating point number between 0 and 1 inclusive, that is the percentage of the weight for this problem
- solved: status of the problem, 1 if the answer was correct, can also be one of the following strings: 'correct_by_student', 'correct_by_scantron', 'credit_attempted', 'incorrect_attempted', 'ungraded_attempted', and the empty string ''
- tries: number of tries used
- award: detailed award determined by how the most recently graded part was graded; possible values:

'EXACT_ANS', 'APPROX_ANS', 'NO_RESPONSE', 'EXTRA_ANSWER', 'MISSING_ANSWER', 'WRONG_NUMBOXESCHECKED', 'ERROR', 'TOO_LONG', 'WANTED_NUMERIC', 'MISORDERED_RANK', 'EXCESS_FILESIZE', 'FILENAME_INUSE', 'INVALID_FILETYPE', 'SIG_FAIL', 'UNIT_INVALID_INSTRUCTOR', 'UNIT_INVALID_STUDENT', 'UNIT_FAIL', 'UNIT_IRRECONCIBLE', 'UNIT_NOTNEEDED', 'NO_UNIT', 'COMMA_FAIL', 'BAD_FORMULA', 'NOT_FUNCTION', 'WRONG_FORMAT', 'INTERNAL_ERROR', 'INCORRECT', 'SUBMITTED', 'SUBMITTED_CREDIT', 'ANONYMOUS', 'ANONYMOUS_CREDIT', 'DRAFT', 'ASSIGNED_SCORE', ''

• status (for bridge task): one of the strings: 'review', 'ungraded', 'fail', 'pass'

Course ID/Number (optional):			

Figure 31: Creating a New Course

Note that in Perl an undefined value, the number 0, the empty string ', the string '0' and an empty list will be evaluated as false, while anything else will be evaluated as true. When a numeric operator like < or == is used, strings are converted into numbers, or the number 0 if the conversion is not possible. Use the eq operator to check string equality.

14.5 Page Maps

Creating a Page map is the same as creating a Sequence map, except that when choosing the name of the resource, the URL will end with ".page". This way, all resources you add in the map editor will appear on one page together. Pages are often used to connect problems in a homework set.

14.6 Courses: Top-level Sequence

In order to view sequences, they need to be part of a **course**.

Courses have a Top-level map which defines the whole course. This Top-Level map will often contain maps corresponding to homework assignments, chapters, or units. To view your maps, you will need to make them part of a course.

When a course is first created a top-level map will be generated. This top-level map will be an "internal" sequence file which is managed using the **Course Editor**. It is also possible to set a course's Top-Level map to be a published sequence, but that is very rarely done. In that case the Course Editor would no longer be used to manage course content.

In the typical case a course's "Main Content" area corresponds to the top-level map, an the Course Editor is used to add, remove or re-order content within it. Users assigned the role of Course Coordinator in a course will upload content or import published content into the course. Folders and sub-folders can be created using the Course Editor, and content uploaded/imported into them.

The content can include published maps (both sequences and pages). Sequences will appear as folders in the Course Contents listing. See the Course Coordination manual for more information.

Your Domain Coordinator may have assigned you rights to request courses. If so, visit your roles screen, and select the "Request course" item in the Functions menu. If not, you should contact your Domain Coordinator to ask about course creation.

15 Tags Used in XML Authoring

LON-CAPA uses a syntax similar to XML and HTML. Here are some basic style guides if you do not know the syntax:

$XML \ \texttt{http://www.w3schools.com/xml/xml_syntax.asp}$

HTML http://www.w3schools.com/html/html5_syntax.asp

Compared to the XML syntax, the LON-CAPA language does not require a prolog at the beginning, and does not require encoding special characters within script elements.

Compared to the HTML syntax, the LON-CAPA language does not require a DOCTYPE, but requires closing all elements. Problem documents do not use the html and body tags. Aside from that, most HTML elements can be used in LON-CAPA documents.

LON-CAPA uses a very simple subset of the XML syntax and there is a lot you do *not* need to know, including but not limited to: CDATA, DTDs, namespaces, and stylesheets. If you search for XML resources on the Internet yourself, you do not need to read about those things to learn how LON-CAPA uses XML/HTML for problems.

15.1 Response Tags

Response tags are the tags used by LON-CAPA to indicate what a student should enter into the system, such as a string answer, clicking on a picture, typing in a formula, etc. They are the core tags of homework problems; a homework problem without at least one response tag is not really a homework problem.

Simple examples of the more complicated tags are available as templates for you to choose from when creating a new problem in your Authoring Space.

15.1.1 numerical response

numerical response implements a numerical answer, it needs an internal **textline** for the the response to go in. It checks all styles of numerical supported in CAPA. The answer can be specified with the **answer** attribute or with an **answergroup**.

Possible attributes are:

- answer: specifies the correct answer, may be either a perl list or scalar
- unit: optional, specifies unit of correct answer, CAPA style
- incorrect: Incorrect Answers. When switched into exam ("bubble sheet") mode, LON-CAPA usually create wrong answers automatically. To specify wrong answers yourself, you need to provide an array of incorrect values in this attribute. You need to provide at least as many incorrects as 1 less than the number of bubbles on the exam. You can provide more if you want to.
- format: string to format the number displayed as the answer. See num in 15.6 for examples.

• preprocess: optional, pre-process Perl subroutine

Hints can be specified with **numericalhint**.

15.1.2 imageresponse

imageresponse implements a image-click answer. **imageresponse** tags should contain a **foilgroup** tag, which contain **foil** tags. Each **foil** tag can contain:

- **image**: required. The delimited text should correspond to a published image resource. Example: <image>/res/adm/includes/templates/man1.jpg</image>. The following image formats are recommended - gif, jpg or png. Other formats may work, but there may be printing or display issues. The image should only appear once per foil.
- rectangle: required. The delimited text specifies a rectangular area that is correct, specified as (x1,y1)-(x2,y2), where x1, x2, y1, and y2 are number corresponding to the x and y coordinates of two corners that define a rectangle which specifies where the right answer for this foil is located on the image. For example, (0,0)-(100,200) will specify that a rectangle 100 pixels wide and 200 pixels tall, situated in the upper left of the image, is correct. At least one rectangle is required; multiple rectangles may be specified.
- **text**: required. The delimited text is printed before the image is shown on the screen. This text is typically used to describe to the student what they are expected to click on.

Possible attributes for **imageresponse** are:

• **max**: the maximum number of foils displayed at once (if more are specified, some will not be displayed)

15.1.3 optionresponse

optionresponse implements a "select from these choices" style question. The choices are specified by the instructor and use the foil structure tags as described in 15.3, with this additional addition:

• **foilgroup**: required to have an *options* attribute which should be a perl list of possible options for the student.

Possible attributes for **optionresponse** are:

- **max**: the maximum number of foils displayed at once (if more are specified, some will not be displayed)
- randomize: set to yes to randomize the order of foils when displayed
- **TeXlayout**: set to horizontal to display foils horizontally for printing

Hints can be specified with **optionhint**.

15.1.4 radiobuttonresponse

radiobuttonresponse implements a true/false question with one correct answer. It uses the foil structure tags as described in 15.3, but the *value* of a foil can only be **true**, **false**, or **unused**. It is possible to use a Perl variable for the value attribute, as long as it can only have a valid value.

Several true foils can be specified, but only one (randomly chosen) will be displayed. Possible attributes for **radiobuttonresponse** are:

- **max**: the maximum number of foils displayed at once (if more are specified, some will not be displayed)
- randomize: set to yes to randomize the order of foils when displayed
- direction: set to horizontal to display foils horizontally

Hints can be specified with **radiobuttonhint**.

15.1.5 dataresponse

dataresponse is an advanced type of response tag that implements a simple data storage and needs an input tag, such as textline, to work correctly. Possible attributes are:

- **name**: internal name for the value. It will have the part id and response id added to it.
- **type**: type of data stored in this response field. It should be one of the types supported by parameter.html
- **display**: string that will be used to describe the field when interfacing with humans.

15.1.6 externalresponse

externalresponse is an advanced type of response tag that implements the ability to have an external program grade a response. It expects either a **textline** or **textfield** inside the tag. Possible attributes are:

- url: url to submit the answer form to. It does not need to be a LON-CAPA machine.
- **answer**: data to post in the form element LONCAPA_correct_answer to the remote site.
- form: hash variable name that will be submitted to the remote site as a HTTP form.

The form sent will consist of

- LONCAPA_student_response full text of what the student entered in the entry field
- LONCAPA_correct_answer contents of the answer attribute

- LONCAPA_language specified language encoding of the requesting resource
- all items in the form attribute if any of these clash with the above, the above values will overwite the value in the form attribute

The response of the remote server needs to be in XML as follows:

- loncapagrade: takes no attributes, but must surround the response.
- awarddetail: required. The delimited text inside must be one of the detailed results that appears in the data storage documentation. CVS:loncapa/doc/homework/datastorage, look for resource.partid.responseid.awarddetail.
- message: optional message to have shown to the student.

Example:

```
<ler
<li><loncapagrade>
<awarddetail>INCORRECT</awarddetail>
<message>
</message to be shown to the students
</message>
</loncapagrade>
```

15.1.7 Attributes For All Response Tags

These response tag attributes are used by all response tags:

- id: If this isn't set, it will be set during the publication step. It is used to assign parameter names in a way that can be tracked if an instructor modifies by hand.
- **name**: optional. If set, it will be used by the resource assembly tool when one is modifying parameters.

15.2 responseparam and parameter

If **responseparam** appears, it should be inside of a response tag. It defines an externally adjustable parameter for the question, which the question can then use to allow other users to customize the problem for their courses without changing the source code of the problem. Possible attributes are:

- **default**: required. Specifies a default value for the parameter.
- name: required. Specifies an internal name for the parameter.
- type: required. Specifies the type of parameter: tolerance, int, float, string, or date. Additional constraints for the type can be specified by adding an underscore and the constraint name to the type, for instance int_pos means *strictly positive integer*.

• **description**: string describing the parameter. This is what is used to talk about a parameter outside of a problem.

parameter is exactly the same as **responseparam**, but should appear outside of a response tag.

15.3 Foil Structure Tags

All response tags that implement a foil structure have an optional arg of max that controls the maximum number of total foils to show.

- **foilgroup**: required. Must surround all foil definitions. Only the optionresponse foilgroup can have attributes.
- foil: required. The foil is defined by what is delimited by the foil tag.
- **conceptgroup**: optional. Surrounds a collection of **foil**. When a problem is displayed, only one of the contained **foil** is selected for display. It has one required attribute **concept**.

15.4 Hint Tags

All of these tags must appear inside a response tag:

- hintgroup: Tag that surrounds all of a hint.
- hintpart: Tag to implement conditional hints. It has a required argument on. When a hint tag named the same as the on attribute evaluates to be correct, the hintpart will show. If no other hintpart is to show then all hintparts with an on value set to "default" will show.
- **numericalhint**: It has all the arguments that **numericalresponse** does, and the required attribute **name** which should be set to the value of which **hintpart** will be shown.
- stringhint: It has all the arguments that stringresponse does, and the required attribute name which should be set to the value of which hintpart will be shown.
- **formulahint**: It has all the arguments that **formularesponse** does, and the required attribute **name** which should be set to the value of which hintpart will be shown.
- **optionhint**: The required attribute **name** should be set to the value of which **hint-part** will be shown.
- radiobuttonhint: The required attribute name should be set to the value of which hintpart will be shown, and the attribute answer should be at least a two element list: first the type (foil or concept) and then either the foil name(s) or the concept string(s), e.g., "('foil', 'greaterthan', 'equal')" if the condition should be triggered by the foils named "greaterthan" or "equal."

• **customhint**: The required attribute **name** should be set to the value of which **hintpart** will be shown. Define the hint condition within an **answer** block inside of the **customhint** block. The condition is defined like how an answer is defined in **customresponse** where you need to return EXACT_ANS to indicate when customhint criteria are met.

15.5 Input Tags

This group of tags implements a mechanism for getting data for students. They will usually be used by a response tag.

- **textfield**: Creates a large text input box. If data appears between the start and end tags, the data will appear in the textfield if the student has not yet made a submission. Additionally, it accepts two attributes: **rows** and **cols**, which control the height and width of the text area respectively. It defaults to 10 rows and 80 columns.
- textline: Creates a single line input element. It accepts one attribute size which controls the width of the textline, defaulting to 20.

Both the **textfield** and **textline** input tags support a **spellcheck** attribute. If present, the text the user types is spellchecked when focus leaves the input field. The value of this attribute specifies the language in which the spellcheck is performed. e.g. <textfield spellcheck='en' /> creates a text field that is spellchecked in English while <textline spellcheck='de' /> creates a text line that is spellchecked in German.

15.6 Output Tags

This group of tags generates useful output.

• algebra: Typesets algebraic expressions

```
<algebra>2x^y+sqrt(3/x^2)</algebra>
```

Expressions are displayed using the math expression display mechanism for the current context. The default is to use the display mechanism the user has selected in preferences. This can be overriden by setting the **display** attribute for the tag. See the section below concerning the $\langle m \rangle$ tag for more information on how the default is set and on the display attribute.

Recognized functions are all trigonometric functions, and the following: exp, abs, logten, log, ln, sqrt, sgn, step, fact, int, lim, funX.

• **chem**: Typesets chemical equation :

```
<chem>02 + 2H2 -> 2H2O</chem>
```

will be rendered: $O_2 + 2 H_2 \rightarrow 2 H_2O$

Syntax Description

- Reactants are separated from products by '->'.
- Individual reactants and products are separated by '+' (leading space is obligatory).
- Numbers preceding the first symbol of a chemical specie are considered to be stoichiometric coefficients.
- Numbers appearing after the first symbol of a chemical specie are considered to be subscripts.
- Superscripts are initialized by '^' and terminated by a space.
- Ionic charges are superscripts composed of a number followed by a sign (i.e. '^2+').

More examples

- $Ca(NO_3)_2$ is written as: $Ca(NO3)_2$
- OH⁻ + H₃O⁺ → 2H₂O is written as: OH⁻ + H3O⁺ -> 2H2O
- $[Co(H_2O)_6]^{2+}$ + 4Cl⁻ → $[CoCl_4]^{2-}$ + 6H₂O is written as: [Co(H2O)6]^2+ + 4Cl^- -> [CoCl4]^2- + 6H2O
- ${}^{3}_{1}H + {}^{2}_{1}H \rightarrow {}^{4}_{2}He + {}^{1}_{0}n \text{ is written as:}$ ^3 1H + ^2 1H → ^4 2He + ^1 On
- **num**: Typesets a number formatted in scientific notation, fixed point, fixed point with commas, fixed point with commas and dollar sign, or in significant digits.

```
<num format="2E">31454678</num> results in 3.15 x 10^7
<num format="2f">31454678</num> results in 31454678.00
<num format="4g">31454678</num> results in 31454678.00
<num format="4g">31454678</num> results in 3145 x 10^7
<num format="4g">31454678</num> results in 314.5
<num format=",2f">31454678</num> results in 31,454,678.00
<num format="$2f">31454678</num> results in 31,454,678.00
<num format="2s">31454678</num> results in 31,454,678.00
<num format="2s">31454678</num> results in 31,000,000
<num format=",2s">31454678</num> results in 31,000,000
```

• parse: to display the parsed view of a variable's contents

```
<script type="loncapa/perl">
   $table='';
   for ($i=1;$i<=10;$i++) {
      $table.='<tr>'.$i.''.&random(1,10,1).'</t>
```

```
$table.='';
</script>
<parse>$table</parse>
```

- **standalone**: Everything in between the start and end tag is shown only on the web and only if the resource is not part of a course.
- displayduedate: This will insert the current due date if one is set in the document. It is generated to be inside a table of 1x1 elements. The displayduedate tag accepts The following attributes:
 - style="plain" Makes the due date appear without any boxing. If the parameter value is other than "*plain*", or if the **style** parameter is omitted, the due date will be displayed within a box.
 - format="fmt_string" Allows you to control the format of the due date. "fmt_string" is an arbitrary string that can contain any of the following formatting items:
 - % a Replaced by the abbreviated weekday name according to the current locale.
 - %A Replaced by the full weekday name according to the current locale.
 - %b The abbreviated month name according to the current locale.
 - % B The full month name according to the current locale.
 - %c The preferred date and time representation for the current locale (the default format string is just this).
 - %C The century number as a two digit integer
 - $\%{\rm d}$ The day of the month as a decimal number. Leading zeroes are shown for single digit day numbers.
 - %D Equivalent to %m/%d/%y
 - % e Like % d but a leadnig zero is replaced by a space.
 - %F Equivalent to %Y-%m-%d
 - %G The four digit year number.
 - %g The two digit year numbger.
 - % H The hour as a two digit number in the range 00 thorugh 23.
 - %I The hour as a two digit number in the range 00 through 12.
 - % The day your the year in the range 001 through 366.
 - %k The hour (24 hour clock), single digits are preceded by a blank.
 - %
l Like %k but using a 12 hour clock.
 - %m The month as a two digit decimal number in the range 01 through 12.
 - $\%{\rm M}$ The minute as a two digit decimal number in the range 00 through 59.
 - %n A newline character.
 - % p AM or PM depending on the time value.
 - %P am or pm.
 - %r The time in am or pm notation.

- %R Time in 24 hour notationn (%H:%M). See also %T below.
- % Number of seconds since midnight of January 1, 1970.
- %S The second as a decimal number int the range 00 through 59.
- %t A horizontal tab character.
- %T The time in 24 hour notation (%H:%M:%S).
- % U Day of the week as a decimal number with Monday as 1.
- %U The week number of the current year in the range 00 through 53. Week 1 is the week containing the first Sunday of the year.
- %V Same as %U but week 1 is the first week with at least 4 days, with Monday being the first day of a week.
- %w Day of the week as a decimal integer in the range 0 through 7, Sunday is 0.
- %W Week number of the current year in the range 00 through 53, where the first Monday of the year is the first day of week 01.
- %x The preferred date notation in the current locale without the time.
- %X The preferred time notation in the current locale without the date.
- %y The year as a decimal number without the century (range 00 through 99).
- %Y The year as a decimal number including the century.
- %% A % character.
- %+ Date and time in the form returned by the Unix date command.
- **displaytitle**: This will insert the title of the problem from the metadata of the problem. Only the first **displaytitle** in a problem will show the title; this allows clean usage of **displaytitle** in LON-CAPA style files.
- window: This creates a link that when clicked shows the intervening information in a pop-up window. By default the window will be 500 pixels wide and 200 pixels tall, and the link text will be a superscript * (so as to look like a footnote). These can be changed using the attributes
 - width controls the starting width of the popup window
 - height controls the starting height of the popup window
 - linktext the text that should appear as the link that causes the creation of the window
 - printtext the text that should appear instead of a footnote when printed

When printing, the included text will get turned into a real footnote.

- windowlink: This creates a link to a resource that comes up in a pop-up window. The link will be the intervening information between the start and the end tag. By default the window will be 500 pixels wide and 200 pixels tall.
 - width controls the starting width of the popup window

- height controls the starting height of the popup window
- \mathbf{href} the address
- togglebox: This creates a toggling box that can be clicked open and close.
 - heading heading text of the box, by default no heading
 - headerbg background color of the header, by default white
 - showtext the text that appears to make the box visible, by default the translation of 'show'
 - hidetext the text that appears to hide the box again, by default the translation of 'hide'

When printing, the included text will be rendered in a visible box.

- m: The inside text is LATEX, and is converted to HTML (or MathML) on the fly. The default is to convert to the display mechanism that the user has selected in preferences. This can be overriden by setting the attribute **display** to one of "**tth**", "**mimetex**" or "**mathjax**" which will force a specific display mechanism. Note that the "**jsmath**" display is deprecated today, and MathJax is used instead when it is specified. If a display attribute is not included, the display mechanism is determined in the following order, with the first one set being the one in effect:
 - 1. In course context: Course-wide default set by Course Coordinator via Settings > Course Settings > Display of resources > Force use of a specific math rendering engine
 - 2. User's own personal preference set by the user hovering over the user's name at top left of a LON-CAPA page, and selecting Preferences > Math display settings
 - 3. Domain default set by a Domain Coordinator
 - 4. System default set for the LON-CAPA version installed on the server (tth in 2.11 and earlier, mathjax in 2.12).

The contents of <m> </m> are interpreted as LaTeX outside math environment, which is why using <m>\$ \$</m> is needed to switch to the LaTeX math environment. However, the "**mathjax**" display (which is used by default in recent versions of LON-CAPA) interprets all the contents of <m> </m> as math, and does not support non-math LaTeX. For content to work well with all the display mechanisms, it is therefore important to never use non-math LaTeX for web targets. Even purely for printing, it is better to avoid using non-math LaTeX, as the printing mechanism might use HTML instead of LaTeX in the future.

If you want variables inside of this tag to be evaluated before the tex gets converted, then use eval="on". For example, <m eval=''on''>\$ \$eqn \$</m>, will evaluate the variable \$eqn first and then use the display mechanism. Anytime you use a variable inside of the m tag, you will want to set eval to on.

For example, put the following in a script in the resource:

\$eqn = "\$a+\$b"; \$eqn = s/\+-/-/g; and in a text area, you can type: <m eval=''on''>\$ \$eqn \$</m>

You will get the equation rendered with no +-, no matter what value \$b may take on.

• randomlabel: This shows a specified image with images or text labels randomly assigned to a set of specific locations. Those locations may also have values assigned to them. A hash is generated that contains the mapping of labels to locations, labels to values, and locations to values. Example:

```
<randomlabel bgimg="URL" width="12" height="45" texwidth="50">
   <labelgroup name="GroupOne" type="image">
     <location x="123" y="456" value="10" />
     <location x="321" y="654" value="20" />
     <location x="213" y="546" value="13" />
     <label description="TEXT-1">IMG-URL</label>
     <label description="TEXT-2">IMG-URL</label>
     <label description="TEXT-3">IMG-URL</label>
   </labelgroup>
   <labelgroup name="GroupTwo" type="text">
     <location x="12" y="45" />
     <location x="32" y="65" />
     <location x="21" y="54" />
     <label>TEXT-1</label>
     <label>TEXT-2</label>
     <label>TEXT-3</label>
   </labelgroup>
  </randomlabel>
```

Possible attributes are:

- bgimg: Either a fully qualified URL for an external image or a LON-CAPA resource. It supports relative references (../images/apicture.gif). The image must either be a GIF or JPEG.
- width: The width of the image in pixels.
- height: The height of the image in pixels.
- texwidth: The width of the image in millimeters.

• **problemtype**: This tag allows you to show or hide output based on what the problemtype parameter is set to in the course. For example:

```
<problemtype mode="show" for="exam,survey">
    <startouttext />
    The formula for the circumference of a circle is 2*pi*r
    <endouttext />
</problemtype>
```

Will only show the output text when the problem is set to the type of exam or survey in the course. The attribute for mode can be set to show or hide. The attribute for for can be problem, exam, survey, or practice.

15.7 Internal Tags

- **labelgroup**: One is required, but multiple are allowed. This declares a group of locations and labels associated with them. Possible attributes are:
 - name: This is the name of the group. A hash with this name will be generated holding the mappings for later use in the problem. For each location a value will be set for which label is there (EX. \$hash{'1'}="TEXT-2"). For locations with values, the hash will contain 2 items, a location to value mapping (\$hash{'value_1'}=10), and a label to value mapping (\$hash{'labelvalue_2'}=10). For all image style of labels there will also be a label description to label URL mapping (\$hash{'image_2'}=IMG-URL). The entry numlocations will also be set to the total number of locations that exist (Note: locations and labels start counting from one.)
 - type: the type of labels in this group, either 'image' or 'text'
 - location: declares a location on the image that a label should appear at. Possible attributes are:
 - * **x**: The x value of the location in pixels.
 - * y: The y value of the location in pixels.
 - * value: An optional scalar value to associate at this location.
 - * **label**: Declaration of a label. If this is a **text** type label, the internal text should be the text of the label (HTML is not currently supported); if this is an **image** type of label, the internal text must be a LON-CAPA resource specification, and the description filed must be set. Possible attributes are:
 - \cdot description: Required field for image labels. It will be used when setting values in the hash.

15.8 Scripting Tags

• **display**: The intervening Perl script is evaluated in the safe space and the return value of the script replaces the entire tag.

- **import**: This causes the parse to read in the file named in the body of the tag and parse it as if the entire text of the file had existed at the location of the tag.
- parserlib: The enclosed filename contains definitions for new tags.
- script: If the attribute type is set to "loncapa/perl" the enclosed data is a Perl script which is evaluated inside the Perl safe space. The return value of the script is ignored. Without a type attribute or with the text/javascript value, the script is considered to be Javascript, and will be executed as such by the web browser.
- scriptlib: The enclosed filename contains Perl code to run in the safe space.
- **block**: This has a required argument **condition** that is evaluated. If the condition is true, everything inside the tag is evaluated; otherwise, everything inside the block tag is skipped.
- notsolved: Everything inside the tag is skipped if the problem is "solved".
- **postanswerdate**: Everything inside the tag is skipped if the problem is before the answer date.
- **preduedate**: Everything inside the tag is skipped if the problem is after the due date.
- randomlist: The enclosed tags are parsed in a stable random order. The optional attribute show="N" restricts the number of tags inside that are actually parsed to no more than N. N can equal the total tags inside. The randomlist tag can be used to randomize problem parts by wrapping the <part> tags with a randomlist tag. Note that when randomlist wraps <part> tags, that all students will work all parts only if show="N" where N is the total number of parts wrapped. When N is less than the total number of parts wrapped, there will be gaps in the assessment chart, and also in the table of submissions for each student, corresponding to those parts which are never available to that particular student. For more examples see Authoring Library Files section 10.1.
- solved: Everything inside the tag is skipped if the problem is "not solved".
- while: This implements a while loop. The required attribute condition is a Perl scriptlet that when evaluated results in a true or false value. If true, the entirety of the text between the whiles is parsed. The condition is tested again, etc. If false, it goes to the next tag.

15.9 Structure Tags

These tags give the problem a structure and take care of the recording of data and giving the student messages.

• **problem**: This must be the first tag in the file. This tag sets up the header of the webpage and generates the submit buttons. It also handles due dates properly.
- **part**: This must be below **problem** if it is going to be used. It does many of the same tasks as **problem**, but allows multiple separate problems to exist in a single file.
- **startouttext** and **endouttext**: These tags are somewhat special. They must have no internal text and occur in pairs. Their use is to mark up the problem so the colorful editor knows what sections should be edited in a text block. They are only used by the colorful editor.
- **comment**: This tag allows one to comment out sections of code in a balanced manner, or to provide a comment description of how a problem works. It only shows up for the edit target, stripped out for all other targets.

16 <script> Tag

16.1 Supported Script Functions

This is a list of functions that have been written that are available in the Safe space scripting environment inside a problem:

- $\sin(x)$, $\cos(x)$, $\tan(x)$
- asin(x), acos(x), atan(x), atan2(y,x)
- $\log(x)$, $\log 10(x)$
- $\exp()$, pow(x,y), sqrt(x)
- abs(x), sgn(x)
- $\operatorname{erf}(\mathbf{x}), \operatorname{erfc}(\mathbf{x})$
- ceil(x), floor(x)
- min(...), max(...)
- factorial(n)
- N%M (modulo function)
- $\sinh(x)$, $\cosh(x)$, $\tanh(x)$
- asinh(x), acosh(x), atanh(x)
- roundto(x,n)
- cas(s,e,l)
- web("a","b","c") or web(a,b,c)
- html("a") or html(a)

- j0(x), j1(x), jn(n,x), jv(y,x)
- y0(x), y1(x), yn(n,x), yv(y,x)
- random
- choose
- tex("a","b") or tex(a,b)
- var_in_tex(a)
- to_string(x), to_string(x,y)
- class(), sec(), classid()
- name(), firstname(), middlename(), lastname(), student_number()
- check_status(partid)
- open_date(partid), due_date(partid), answer_date(partid)
- open_date_epoch(partid), due_date_epoch(partid), answer_date_epoch(partid)
- submission(partid, response id, version)
- currentpart()
- sub_string()
- array_moments(array)
- format(x,y),prettyprint(x,y,target),dollarformat(x,target)
- languages
- map(...)
- caparesponse_check
- caparesponse_check_list
- parameter_setting(name,partid)
- EXT()
- stored_data(name,partid)
- wrong_bubbles(correct,lower,upper,step,@given)

We also support these functions from Math::Cephes

```
bdtr: Binomial distribution
bdtrc: Complemented binomial distribution
bdtri: Inverse binomial distribution
btdtr: Beta distribution
chdtr: Chi-square distribution
chdtrc: Complemented Chi-square distribution
chdtri: Inverse of complemented Chi-square distribution
fdtr: F distribution
fdtrc: Complemented F distribution
       Inverse of complemented F distribution
fdtri:
gdtr: Gamma distribution function
gdtrc:
       Complemented gamma distribution function
nbdtr: Negative binomial distribution
nbdtrc: Complemented negative binomial distribution
nbdtri: Functional inverse of negative binomial distribution
ndtr: Normal distribution function
ndtri: Inverse of Normal distribution function
pdtr: Poisson distribution
pdtrc: Complemented poisson distribution
pdtri: Inverse Poisson distribution
stdtr: Student's t distribution
stdtri: Functional inverse of Student's t distribution
```

See https://metacpan.org/pod/Math::Cephes for more information

Support for complex numbers in the Safe space scripting environment is available via the LONCAPA::LCMathComplex package, which is the standard Math::Complex module available from CPAN, modified to work in Safe space.

These functions from LONCAPA::LCMathComplex are available:

Re(\$z) Im(\$z) arg(\$z) abs(\$z)

where \$z is a complex number created using the Cartesian form, where \$a and \$b are numbers in one of the following ways:

```
$z = LONCAPA::LCMathComplex->make($a, $b);
$z = cplx($a, $b);
$z = $a + $b*i;
```

or created using the polar form, where \$m and \$n are numbers, in which the first argument is the modulus, and the second is the angle in radians:

```
$z = LONCAPA::LCMathComplex->emake($m, pi/$n);
$z = cplxe($m, pi/$n);
```

Where there is no overlap with function names used for Math::Cephes functions, then you can just use the LCMathComplex functions directly, e.g.. &cplx(), &Re(), &Im(), but where there is overlap, as is the case for tanh(), to ensure the function from LCMathComplex is called, include the full namespace identifier, e.g., LONCAPA::LCMathComplex::tanh().

See: https://metacpan.org/pod/Math::Complex for more information.

16.2 Script Variables

- \$external::target set to the current target the xml parser is parsing for
- \$external::part set to the *id* of the current problem <part>; zero if there are no <part>
- \$external::gradestatus set to the value of the current resource.partid.solved value
- \$external::datestatus set to the current status of the clock either CLOSED, CAN_ANSWER, CANNOT_ANSWER, SHOW_ANSWER, or UNCHECKEDOUT
- \$external::randomseed set to the number that was used to seed the random number generator
- \$pi set to PI
- \$rad2deg converts radians to degrees
- \$deg2rad converts degrees to radians

16.3 Table: LON-CAPA Functions

LON-CAPA Function	Description
$\&\sin(\$x), \&\cos(\$x), \&\tan(\$x)$	Trigonometric functions where x is in radians.
	\$x can be a pure number, i.e., you can call
	$\&\sin(3.1415)$
$\& asin(\$x), & \& acos(\$x), & \& atan(\$x), \\ \& atan(\$x), & \& atan(\$x), & \& atan(\$x), \\ \& atan(\$x), & \& atan(\$x), & \& atan(\$x), & \& atan(\$x), \\ \& atan(\$x), & $	Inverse trigonometric functions. Return value
&atan2(\$y,\$x)	is in radians. For asin and acos the value of x
	must be between -1 and 1. The atan2 returns
	a value between -pi and pi the sign of which is
	determined by y. \$x and \$y can be pure num-
	bers
$\&\log(\$x), \&\log10(\$x)$	Natural and base-10 logarithm. \$x can be a
	pure number
&exp(\$x), &pow(\$x,\$y), &sqrt(\$x) Exponential, power and square root,	
	and $/x$. x and y can be pure numbers

LON-CAPA Function	Description		
&abs(\$x), &sgn(\$x)	Abs takes the absolute value of x while $sgn(x)$		
	returns 1, 0 or -1 depending on the value of x.		
	For $x>0$, $sgn(x) = 1$, for $x=0$, $sgn(x) = 0$ and		
	for $x < 0$, $sgn(x) = -1$. x can be a pure number		
& erf(\$x), & erfc(\$x)	Error function. $erf = 2/sqrt(pi)$ integral $(0,x)$		
	et-sq and $erfx(x) = 1.0 - erf(x)$. \$x can be a		
	pure number		
&ceil(x), &floor(x)	Ceil function returns an integer rounded up		
	whereas floor function returns and integer		
	rounded down. If x is an integer than it re-		
	turns the value of the integer. \$x can be a pure		
	number		
$\&\min(), \&\max()$	Returns the minimum/ maximum value of a		
	list of arguments if the arguments are numbers.		
	If the arguments are strings then it returns a		
	string sorted according to the ASCII codes		
&factorial(\$n)	Argument (n) must be an integer else it will		
	round down. The largest value for n is 170. \$n		
	can be a pure number		
\$N%\$M	N and M are integers and returns the remainder		
	(in integer) of N/M. N and M can be pure		
	numbers		
$\frac{\text{dsinh}(\text{sx}), \text{dcosh}(\text{sx}), \text{dtanh}(\text{sx})}{1 + \frac{1}{2}}$	Hyperbolic functions. \$x can be a pure number		
xasinh(x), xacosh(x), xatanh(x)	Inverse hyperbolic functions. \$x can be a pure		
	number		
&format(\$x,'nn')	Display or format x as nn where nn is nF or		
	nE or nS and n is an integer.		
\$expr=&math_calculus_expression()	Creates Math::Calculus::Expression object.		
	Methods are: $\frac{1}{2} \exp(\frac{1}{2} \frac{1}{2} \frac{1}{$		
	$\frac{1}{2}$		
	Usinipiny, Sexpr-EgetExpression – see		
	at even are for details		
$(\mathbf{e}_{2}, \mathbf{e}_{33}) - \mathbf{e}_{22}$	at chaining for details.		
$(aa, au) = \infty \operatorname{conv}_{\operatorname{eng}} \operatorname{conv}_{\operatorname{eng}} (ax, ab)$	to answer \$2 and corresponding unit \$4 in on		
	sincering format i.e. the answer is scaled by		
	powers of ton, and an appropriate profix from:		
	munn faz y k M G T P E Z V precedes the		
	hase unit. Called in a script block to generate		
	variables to assign to answer and unit attributes		
	of numerical response tag		
(\$a,\$u)=&conv_eng_format(\$x,\$b)	Converts numerical value \$x and base unit \$b to answer \$a and corresponding unit \$u in engineering format, i.e., the answer is scaled by powers of ten, and an appropriate prefix from: m u n p f a z y k M G T P E Z Y precedes the base unit. Called in a script block to generate variables to assign to answer and unit attributes of numerical response tag.		

LON-CAPA Function	Description
&prettyprint(\$x,'nn','optional target')	Note that tag <num> can be used to do</num>
	the same thing. Display or format \$x as nn
	where nn is nF or nE or nS and n is an integer.
	Also supports the first character being a \$, it
	then will format the result with a a call to &dol-
	larformat() described below. If the first charac-
	ter is a , it will format it with commas grouping
	the thousands. In S mode it will from the
	number to the specified number of significant
	figures and display it in F mode. In E mode it
	will attempt to generate a pretty x10 ³ rather
	than a E3 following the number, the 'optional
	target' argument is optional but can be used to
	force & prettyprint to generate either 'tex' out-
	put, or 'web' output, most people do not need
	to specify this argument and can leave it blank.
&dollarformat(\$x,'optional target')	Reformats x to have a $(or \ if in tex mode)$
	and to have, grouping thousands. The 'optional
	target argument is optional but can be used to
	force & prettyprint to generate either 'tex' out-
	put, or 'web' output, most people do not need
	to specify this argument and can leave it blank.
Option 1 - $\text{SDest} = \text{Manguages}()$	
Option 2 - $@an = & anguages()$	
Option 3 - \Rightarrow Dest =	Boturns the best language to use in the first
Option 4 @oll	two options returns the languages codes in the
Option 4 - @an =	preference order of the user. In the second two
anguages(\@desned_languages)	examples returns the best matches from a list
	of desired language possibilities
&roundto(\$x \$n)	Bounds a real number to n decimal points \$x
	and $\$ can be pure numbers
&cas(\$s \$e \$1)	Evaluates the expression \$e inside the sym-
	bolic algebra system \$s Currently the
	Maxima symbolic math system ('maxima')
	and the R statistical computing system
	('R') are implemented. \$1 is an optional
	comma-separated list of libraries. Example:
	&cas('maxima','diff(sin(x)/cos(x),x,2)')

LON-CAPA Function	Description
&implicit_multiplication(\$f)	Adds mathematical multiplication operators
	to the formula expression \$f where only
	implicit multiplication is used. Exam-
	ple: &implicit_multiplication('2(b+3c)') re-
	turns $2^*(b+3^*c)$
&web("a","b","c") or &web(\$a,\$b,\$c)	Returns either a, b or c depending on the output
	medium. a is for plain ASCII, b for tex output
	and c for html output
&html("a") or &html(\$a)	Output only if the output mode chosen is in
	html format
&j0(\$x), &j1(\$x), &jn(\$m,\$x), &jv(\$y,\$x)	Bessel functions of the first kind with orders 0,
	1 and m respectively. For $jn(m,x)$, m must be
	an integer whereas for $jv(y,x)$, y is real. x can
	be a pure number. \$m must be an integer and
	can be a pure integer number. \$y can be a pure
	real number
&y0(\$x), &y1(\$x), &yn(\$m,\$x), &yv(\$y,\$x)	Bessel functions of the second kind with orders
	0, 1 and m respectively. For $yn(m,x)$, m must
	be an integer whereas for $yv(y,x)$, y is real. x
	can be a pure number. \$m must be an integer
	and can be a pure integer number. \$y can be a
	pure real number
&random(\$1,\$u,\$d)	Returns a uniformly distributed random num-
	ber between the lower bound, I and upper
	bound, u in steps of d. d is optional. If omitted,
	a step of 1 is used. \$1, \$u and \$d can be pure
	numbers.
&choose(\$1,)	Choose the ith item from the argument list. i
	must be an integer greater than 0 and the value
	of 1 should not exceed the number of items. \$i
	can be a pure integer

LON-CAPA Function	Description
Option 1 -	
$&\operatorname{map}(\${\operatorname{seed}},[\\${w},\\${x},\\${y},\\${z}],[\$a,\$b,\$c,\$d])$	
or	
Option 2 -	
map(seed, @mappedArray, [sa, b, c, d])	
Option 3 - $@mappedArray =$	
↦(\$seed, [\$a, \$b, \$c, \$d])	
Option 4 - $(\$w,\$x,\$y,\$z) =$	Assigns to the variables \$w, \$x, \$y and \$z the
map(seed, @a)	values of the \$a, \$b, \$c and \$c (A, B, C and
Option 5 - $@Z = \↦(\$seed, @a)$	D). The precise value for \$w depends on the
where $a=A'$	seed. (Option 1 of calling map). In option 2,
\$b='B'	the values of \$a, \$b are mapped into the ar-
\$c='B'	ray, @mappedArray. The two options illustrate
\$d='B'	the different grouping. Options 3 and 4 give a
\$w, \$x, \$y, and \$z are variables	consistent way (with other functions) of map-
	ping the items. For each option, the group can
	be passed as an array, for example, [\$a,\$b,\$c,\$d]
	$=$ \@a. And Option 5 is the same as option 4,
	where the array of results is saved into a single
	array rather than an array of scalar variables.
Option 1 -	
$ \text{\&rmap}(\$\text{seed}, [\\$w, \\$x, \\$y, \\$z], [\$a, \$b, \$c, \$d]) $	
OT	
Option 2 -	
$\text{\ensuremath{\&}rmap(\$seed, @rmappedArray, [\$a, \$b, $c, $d])}$	
Option 3 - $@rmapped_array =$	
&rmap(\$seed, [\$a, \$b, \$c, \$d])	
Option 4 - $(\$w,\$x,\$y,\$z) =$	The rmap functions does the reverse action of
$\text{\&rmap}(\text{\$seed}, \mathbb{Q}a)$	map if the same seed is used in calling map and
Option 5 - $@Z = \↦(\$seed, @a)$	rmap.
where $a=A'$	
\$b='B'	
\$c='B'	
\$d='B'	
\$w, \$x, \$y, and \$z are variables	
\$a=&xmlparse(\$string)	You probably should use the tag <parse> in-</parse>
	stead of this function. Runs the internal parser
	over the argument parsing for display. Warn-
	ing This will result in different strings in differ-
	ent targets. Don't use the results of this func-
	tion as an answer.
&tex(\$a,\$b), &tex("a","b")	Returns a if the output mode is in tex otherwise
	returns b

LON-CAPA Function	Description	
&var_in_tex(\$a)	Equivalent to tex("a"," ")	
&to_string(\$x), &to_string(\$x,\$y)	If x is an integer, returns a string. If	
	x is real than the output is a string with	
	format given by y. For example, if $x =$	
	12.3456 , &to_string(x,".3F") = 12.345 and	
	$\text{\&to_string}(x,".3E") = 1.234E+01.$	
&class(), $&$ sec(), $&$ classid()	Returns null string, class descriptive name, sec-	
	tion number, class id, set number and null	
	string.	
&name(), &student_number(), &firstname(),	Return the full name in the following format:	
&middlename(), &lastname()	lastname, firstname initial. Student_number re-	
	turns the student 9-alphanumeric string. The	
	functions firstname, middlename, and lastname	
	return just that part of the name. If undefined,	
	the functions return null.	
✓_status(\$partid)	Returns a number identifying the current sta-	
	tus of a part. True values mean that a part is	
	"done": either unanswerable because of tries ex-	
	haustion, or fully correct, or only partially cor-	
	rect (and retries not permitted). A false value	
	means that a part can still be attempted. If	
	spart is unspecified, it will check either the cur-	
	check the status of provious $\langle \text{part} \rangle$. The full	
	set of return codes are: 'undef' moans it is unat	
	tempted 0 means it is attempted but still has	
	tries and is either wrong (or partially correct	
	retries allowed) 1 means it is fully correct or	
	partially correct (no retries) 2 means they have	
	exceeded maximum number of tries. 3 means it	
	is after the answer date.	
&open_date(\$partid). &due_date(\$partid).	Problem open date, due date and answer date in	
&answer_date(\$partid)	local human-readable format. Part 0 is chosen	
	if \$partid is omitted.	
&open_date_epoch(\$partid),	Problem open date, due date and answer date	
&due_date_epoch((\$partid), &an-	in seconds after the epoch (UTC), which can be	
swer_date_epoch((\$partid)	used in calculations.	

LON-CAPA Function	Description
&submission(\$partid,\$responseid,\$version,	Returns what the student submitted for re-
&submission(\$partid,\$responseid,\$version, \$encode,\$cleanupnum,\$mapalias)	Returns what the student submitted for re- sponse \$responseid in part \$partid. You can get these IDs from the XML-code of the problem. Use 0 as \$partid for problems without parts. \$version is optional and returns the \$version- th submission of the student that was graded. If \$version is 0 or omitted, the latest submis- sion is returned. \$encode is also optional and allows the author to explicitly encode the re- turned string. It's up to the author to take care of properly escaping all characters which might be interpreted by the browser. \$cleanupnum is also optional, and supports clean-up of the re-
¶meter setting(\$name \$partid)	also optional, and supports clean-up of the re- trieved submission. It is a reference to a hash, with one or more of the following: exponent $=>$ 1, comma $=>$ 1, letterforzero $=>$ 1, spaces $=>$ 1, format $=>$ 'ns' (where n is an integer, i.e., number of significant digits). For example, to convert a student submission of 11,300 to 11300 include { comma $=>$ 1, } as the fifth arg. \$ma- palias is also optional, and supports retrieval of the submission for a response item in a differ- ent problem in the course, for which a (unique) mapalias has been set. The default (mapalias not defined) is to retrieve the submission for the specified part and response IDs in the current problem. Beturns the parameter setting \$name_Partid is
	optional.
&stored_data(\$name,\$partid)	Returns the stored data \$name. Partid is optional.
&wrong_bubbles(\$correct,\$lower,\$upper,\$step,@	giken)rns an array that can be used for wrong answers in numerical responses. The first ar- gument is the correct answer, the next argu- ments are the lower and upper boundaries for the bubbles, as well as the step size. The next argument is an optional array of wrong answers that should be included.
¤tpart()	Returns the ID of the current part.
&input_id(part_id, response_id, textline_id)	Returns the HTML id of the input field. This is useful in Javascript scripts to get a safe reference to a response textline field with document.getElementById().

LON-CAPA Function	Description
Not implemented	Get and set the random seed.
⊂_string(\$a,\$b,\$c) perl substr function. However, note the differences	Retrieve a portion of string a starting from b and length c. For example, $a = Welcome$ to LON-CAPA"; \$result=⊂_string(\$a,4,4); then \$result is "come"
@arrayname Array is intrinsic in perl. To access a specific element use \$arrayname[\$n] where \$n is the \$n+1 element since the array count starts from 0	"xx" can be a variable or a calculation.
@B=&array_moments(@A)	Evaluates the moments of an array A and place the result in array B[i] where $i = 0$ to 4. The contents of B are as follows: B[0] = number of elements, B[1] = mean, B[2] = variance, B[3] = skewness and B[4] = kurtosis.
&min(@Name), &max(@Name)	In LON-CAPA to find the maximum value of an array, use &max(@arrayname) and to find the minimum value of an array, use &min(@arrayname)
undef @name	To destroy the contents of an array, use
@return_array=&random_normal	Generate \$item_cnt deviates of normal distri-
(\$item_cnt,\$seed,\$av,\$std_dev)	bution of average \$av and standard deviation \$std_dev. The distribution is generated from seed \$seed
@return_array=&random_beta (\$item_cnt,\$seed,\$aa,\$bb) NOTE: Both \$aa and \$bb MUST be greater than 1.0E-37.	Generate $item_cnt$ deviates of beta distribu- tion. The density of beta is: X^($aa-1$) *(1- X)^($bb-1$) /B(aa,bb) for 0 <x<1.< td=""></x<1.<>
@return_array=&random_gamma (\$item_cnt,\$seed,\$a,\$r) NOTE: Both \$a and \$r MUST be positive.	Generate $item_cnt$ deviates of gamma distribution. The density of gamma is: $(a^{**}r)/gamma(r) * X^{**}(r-1) * exp(-a^{*}X)$.
@return_array=&random_exponential (\$item_cnt,\$seed,\$av) NOTE: \$av MUST be non-negative.	Generate \$item_cnt deviates of exponential dis- tribution.
@return_array=&random_poisson (\$item_cnt,\$seed,\$mu) NOTE: \$mu MUST be non-negative.	Generate \$item_cnt deviates of poisson distribution.
@return_array=&random_chi (\$item_cnt,\$seed,\$df) NOTE: \$df MUST be positive.	Generate \$item_cnt deviates of chi_square dis- tribution with \$df degrees of freedom.
@return_array=&random_noncentral_chi (\$item_cnt,\$seed,\$df,\$nonc) NOTE: \$df MUST be at least 1 and \$nonc MUST be non-negative.	Generate \$item_cnt deviates of noncen- tral_chi_square distribution with \$df degrees of freedom and noncentrality parameter \$nonc.

LON-CAPA Function	Description
@return_array=&random_f	Generate \$item_cnt deviates of F (variance ra-
(\$item_cnt,\$seed,\$dfn,\$dfd) NOTE: Both	tio) distribution with degrees of freedom \$dfn
\$dfn and \$dfd MUST be positive.	(numerator) and \$dfd (denominator).
@return_array=&random_noncentral_f	Generate \$item_cnt deviates of noncentral F
(\$item_cnt,\$seed,\$dfn,\$dfd,\$nonc) NOTE:	(variance ratio) distribution with degrees of
\$dfn must be at least 1, \$dfd MUST be	freedom \$dfn (numerator) and \$dfd (denomi-
positive, and \$nonc must be non-negative.	nator). \$nonc is the noncentrality parameter.
@return_array=&random_multivariate_normal	Generate \$item_cnt deviates of multivari-
$($item_cnt, $seed, @mean, @covar)$ NOTE:	ate_normal distribution with mean vector
@mean should be of length p array of real	@mean and variance-covariance matrix.
numbers. @covar should be a length p array of	
references to length p arrays of real numbers	
(i.e. a p by p matrix.	
@return_array=&random_multinomial	Returns single observation from multinomial
(\$item_cnt,\$seed,@p) NOTE: \$item_cnt is	distribution with \$item_cnt events classified into
rounded with int() and the result must be	as many categories as the length of @p. The
non-negative. The number of elements in @p	probability of an event being classified into cat-
must be at least 2.	egory i is given by ith element of @p. The ob-
	servation is an array with length equal to @p,
	so when called in a scalar context it returns the
	length of @p. The sum of the elements of the
	obervation is equal to \$item_cnt.
@return_array=&random_permutation	Returns @array randomly permuted.
(\$seed,@array)	
@return_array=&random_uniform	Generate \$item_cnt deviates from a uniform dis-
(\$item_cnt,\$seed,\$low,\$high) NOTE: \$low	tribution.
must be less than or equal to \$high.	
@return_array=&random_uniform_integer	Generate \$item_cnt deviates from a uniform dis-
(\$item_cnt,\$seed,\$low,\$high) NOTE: \$low and	tribution in integers.
\$high are both passed through int(). \$low must	
be less than or equal to \$high.	
@return_array=&random_binomial	Generate \$item_cnt deviates from the binomial
(\$item_cnt,\$seed,\$nt,\$p) NOTE: \$nt is rounded	distribution with \$nt trials and the probability
using int() and the result must be non-negative.	of an event in each trial is \$p.
\$p must be between 0 and 1 inclusive.	
@return_array=&random_negative_binomial	Generate an array of \$item_cnt outcomes gen-
(\$item_cnt,\$seed,\$ne,\$p) NOTE: \$ne is rounded	erated from negative binomial distribution with
using int() and the result must be positive. \$p	\$ne events and the probability of an event in
must be between 0 and 1 exclusive.	each trial is \$p.

The &EXT() external function is extremely powerful, and is used to access parameters and submission values. It can be used within scripts and also within cell formulas in the grading spreadsheet. Some examples can be found by browsing in the repository to /res/msu/albertel/test/ext_examples.html. The &EXT() function can be used to obtain values for the same parameters as are retrived by some of the other (newer) helper functions summarized in the table above, such as &firstname() which is equivalent to &EXT('environment.firstname'), and ¶meter_setting(\$name,\$partid) is equivalent to &EXT('resource.'.\$partid.'.'.\$name). In such cases the newer (specialized) functions are preferred to &EXT() on the basis of ease of use.

CAPA Functions	LON-CAPA	Differences (if any)

	&jv(\$y,\$x)	tained in one function, $jn(m,x)$
		where m takes the value of 0 ,
		1 or 2. $jv(y,x)$ is new to LON-
		CAPA.

16.4 Table: CAPA vs. LON-CAPA Function Differences

CAPA Functions	LON-CAPA	Differences (if any)
yn(m,x)	&y0(\$x), &y1(\$x), &yn(\$m,\$x), &yv(\$y,\$x)	In CAPA, y0, y1 and yn are contained in one function, yn(m,x) where m takes the value of 0, 1 or 2. $yv(y,x)$ is
random(l,u,d)	&random(\$l,\$u,\$d)	In CAPA, all the 3 arguments must be of the same type. However, now you can mix the type
choose(i,)	&choose(\$i,)	
/MAP(seed;w,x,y,z;a,b,c,d)	Option 1 $↦(\$seed,[\\$w,\\$x,\\$y,\\$z],[\$a,\$b]$ or Option 2 - $↦(\$seed,\@mappedArray,[\$a,\$b,"]$ Option 3 - $@mappedArray =$ ↦(\$seed,[\$a,\$b,\$c,\$d]) Option 4 - $(\$w,\$x,\$y,\$z) =$ $↦(\$seed,\@a)$ where $\$a=`A'$ \$b=`B' \$c=`B' \$d=`B' \$w, \$x, \$y, and \$z are variables	 \$c,\$d]) \$c,\$d]) \$c,\$d]) In CAPA, the arguments are divided into three groups separated by a semicolon ;. In LON-CAPA, the separation is done by using [] brackets or using an array @a. Note the backslash (\) before the arguments in the second and third groups.

CAPA Functions	LON-CAPA	Differences (if any)
rmap(seed;a,b,c,d;w,x,y,z)	$\begin{array}{l} \textbf{LOIN-CAPA} \\ \hline \text{Option} & 1 & - \\ \& rmap(\$seed, [\\$w, \\$x, \\$y, \\$z], [\$a, \$l] \\ or \\ Option & 2 & - \\ \& rmap(\$seed, \@rmappedArray, [\$a, \$l] \\ Option & 3 & - & @rmapped_array & = \\ \& rmap(\$seed, [\$a, \$b, \$c, \$d]) \\ Option & 4 & - & (\$w, \$x, \$y, \$z) & = \\ \& rmap(\$seed, \@a) \\ where \\$a = `A` \\ \$b = `B` \end{array}$	 Differences (if any) p,\$c,\$d]) In CAPA, the arguments are divided into three groups separated by a semicolon ;. In LON-CAPA, the separation is
	<pre>\$b='B' \$c='B' \$d='B' \$w, \$x, \$y, and \$z are variables</pre>	done by using [] brackets (with create an unamed vector ref- erence) or using an array @a. Note the backslash (\) before the arguments in the second and third groups (Which cause Perl to send to variable loca- tions rather than the variable values, similar to a C pointer).
NOT IMPLEMENTED IN CAPA	\$a=&xmlparse(\$string)	New to LON-CAPA
tex(a,b), tex("a","b")	&tex(\$a,\$b), &tex("a","b")	
var_in_tex(a)	&var_in_tex(\$a)	
$to_string(x), to_string(x,y)$	&to_string(\$x), &to_string(\$x,\$y)	
capa_id(), class(), section(), set(), problem()	&class(), &sec()	capa_id(), set() and problem() are no longer used. Currently, they return a null value.
name(), student_number()	&name(), &student_number()	
open_date(), due_date(), answer_date()	&open_date(), &due_date(), &an- swer_date()	Output format for time is changed slightly. If pass noon, it displayspm else it displays am. So 23:59 is displayed as 11:59 pm.
get_seed(), set_seed()	Not implemented	
sub_string(a,b,c)	⊂_string(\$a,\$b,\$c) perl substr function. However, note the differ- ences	Perl intrinsic function, sub- str(string,b,c) starts counting from 0 (as opposed to 1). In the example to the left, sub- str(\$a,4,4) returns "ome ".

CAPA Functions	LON-CAPA	Differences (if any)
array[xx]	@arrayname Array is intrinsic in	In LON-CAPA, an array is de-
	perl. To access a specific element	fined by @arrayname. It is not
	use $\frac{1}{n}$ where $\frac{1}{n}$ is the	necessary to specify the dimen-
	n+1 element since the array count	sion of the array.
	starts from 0

17 Bridge Task

Bridge Tasks (BTs) are open-ended, performance-based assessments. BTs are based on a mastery-model of assessment and evaluated on a pass-fail basis. You may use BTs in a variety of ways, from supporting the scoring of a final project, to individual lab assignments. See Introduction to Bridge Task (17.1) for a more in-depth explanation to Bridge Tasks. The main features of a bridge task (17.2) section gives the differences between BTs and other assessments.

An author creates a bridge task either by writing the XML code or by using the edit mode and publishing it. A course coordinator must then place the Bridge Task resource in his/her course's document list. The section on Bridge Task Creation (17.3) describes how to author as well as set up these Bridge Tasks.

Once the bridge task is created and published, the course coordinator must insert the resource in the course's document list (See Setting Up a Bridge Task 17.6). The course coordinator may also create slots to limit the place/time the bridge task may be opened (See Using Slots in Bridge Task 17.6.1). This resource may also be placed inside conditionals resources so that it is accessible only after a particular condition has been met (see Bridge Task and Conditional Resources 17.6.2).

Once the course coordinator has set up the Bridge Task the student is able to open and use the bridge task. A Bridge Task hand-in process using portfolio files may be used by the instructors or students if they wish (See Handing In Bridge Task Files 17.7).

17.1 Introduction to Bridge Task

Bridge tasks consist of one or more individual tasks that describe what the student is to do, usually in the form of a problem to solve. LON-CAPA supports the creation of multiple versions of each task, so that each student may receive a mix of randomly assigned tasks to perform. Students use LON-CAPA to view the bridge task. LON-CAPA supports the scheduling of BTs to restrict access by IP address range and to allow students to schedule slots of time to take a BT.

When students complete a BT, they upload files they have created for grading. Files are uploaded using LON-CAPA's portfolio system.

LON-CAPA supports the creation of scoring rubrics associated with each individual task to guide graders and ensure inter-rater reliability among multiple graders in a course. Instructors specify criteria to assign an overall score to a BT based on the scores of the individual rubrics.

BTs are used in Michigan State University's CSE 101 course. The course is designed to teach computer competencies by having students solve problems using a variety of computer software (MS-Word, MS-Excel, World Wide Web, and MS Access). In CSE 101, BTs are used for summative assessment, the majority of students' grades are based upon the BTs. Here, students must successfully pass a BT before attempting the next BT. A student's final course grade is based on the highest level BT passed. The CSE 101 class is quite large, approximately 2000 students per semester. Students may take up to one BT per week; typically there are over 14,000 BTs administered per semester. Thus there is a need to quickly and accurately access students. LON-CAPA successfully supports the load requirements.

17.2 Bridge Task Features

There are many ways in which BTs differ from other assessments.

- 1. Multiple Versions. There are multiple versions of a BT. A person taking a BT may receive a different version than the person taking the same BT sitting next to him or her. To create BTs that have different versions, the instructors who created the BT will create multiple sub-questions. The BT engine then chooses one of the sub questions and gives that sub question to the student, thus creating multiple versions.
- 2. Essay/task based. Bridge task questions open-ended. Users create files which they upload and submit to the system.
- 3. **Rubric-Based Grading**. Each question in a bridge task has scoring rubrics, criteria, associated with them. These criteria are used as the basis of grading. The grading page provides the criteria checklist on which the grader enters whether a student passes or fails each criterion. This ensures inter-rater reliability among multiple graders.
- 4. Mandatory and Optional Criteria. Some criteria can be made mandatory, that is a student will fail if the student does not pass that criteria. Some criteria are optional and the student must pass a certain number of these optional criteria. Criteria are associated with questions, which can also be made optional or mandatory. LON-CAPA calculates whether a student has passed or fail based on the number of mandatory and optional questions the student has passed.
- 5. Automatic Bookkeeping. The system calculates whether the student has passed a BT or not and records it into the database. The system stores
 - a complete record of the BT each student received
 - when each student's BT was administered
 - the BT instance
 - the files the student turned in
 - the associated grading criteria
 - the grading results (and history of grading, including grader ID)
- 6. Sequential Bridge Tasks. The system can be set in such a way that a student can only take a certain bridge task after passing the previous bridge task on the list. This is done using conditionals in LON-CAPA. There are other ways to use conditionals and bridge tasks to customize the usage of bridge tasks in a course.
- 7. Slots. Slots can be created to relate students with time and location. This allows control of where and when a student can take a bridge task.
- 8. **Proctor Authentication**. Slots also allow a particular proctor to be in a particular location for a bridge task. Each student who is scheduled to take the bridge task must be authenticated by the proctor.

Figure 32: Bridge Task creation flowchart

17.3 Authoring Bridge Task

There are multiple steps for creating a bridge task and setting the bridge task up so that the students is able to use it. The flow of the bridge task creation process is shown in figure 32.

There are two ways of creating the bridge task. The first method is to directly edit the XML file being used (See Bridge Task XML Editing 17.4). The second method is to use the LON-CAPA online edit mode (See Bridge Task Mode Editing 17.5).

Once the bridge task is created and published, the course coordinator must insert the resource in the course's document list (See Setting Up Bridge Task 17.6). The course coordinator may also create slots to allow for multiple place/time the bridge task may be opened or to allow for multiple separate attempts at the bridgetask (See Using Slots in Bridge Task 17.6.1). As with any resource, the map it is in may use conditionals to control access to the resources based on other information in the course. (For example, the section of a user, the passing of a prior bridgetask, etc.)

17.4 Bridge Task XML Editing

The LON CAPA .task format is an XML file used directly by LON CAPA. XML is a markup language, much like HTML. A primer on XML is given in section 9. An XML file contains elements in tags, and elements may contain attributes. The syntax, spelling (including capitalization) of the XML file must be exact, otherwise the XML file will generate errors.

The online editor for the .task format is discussed in the next section. This section describes creating the .task file by simply using a text editor such as Notepad.

The .task format consists of four parts:

- The header, which contains information about the file itself. The header can be copied from this documentation as is (see .Task Headers 17.4.1)
- Parameter information. This part consists of the possible values for various parameters in the Bridge Task (see .Task Parameter and Variable 17.4.2)
- Questions section. This part consists of the actual text the user sees as well as all criteria and questions (see .Task Question 17.4.3)
- Footer section. This part consists of the actual text the user sees as well as all criteria and questions (see .Task Finishing Up 17.4.4)

Once all parts are created, the author must publish the file so that it is accessible by course coordinators (see .Task Finishing Up 17.4.4).

17.4.1 .Task Headers

The root node of the .task format is the task element, which is an XML element written as follows:

<Task OptionalRequired='0'>

The Task element signifies that this is a bridge task. The OptionalRequired is a mandatory attribute, and the value (0 in this case) determines how many optional questions the student must pass.

17.4.2 .Task Parameter and Variable

To create difference versions of Bridge Tasks for each student, parts of the questions are defined using variables. Each variable contains multiple instances of possible values and LON-CAPA randomly selects an instance to give to the student.

All variables are placed inside a Setup element. Each setup element has an id attribute which contains the name of the variable. The possible instances or values of those variables are placed inside the setup element inside an Instance tag. Each Instance element has two mandatory attributes, the OptionalRequired attribute which should be set to 0, and the unique id of that instance. The value of the id attribute can be any text as long as it is unique throughout the document.

The actual data of the instance is placed inside InstanceText tags. Currently the instance data is created with a loncapa/perl script. In this script the parameters of the variable are set. The syntax to set the parameter of a variable is '\$variableName {fieldname} = "fieldValues"'. The variable name is taken from the attribute id from the Setup element, the field name is the name of the parameter the author sets, and the fieldValue is simply the value of the field. The first parameter that must be set is the instance field, with the value being an identifier of the instance.

The example below shows a portion of the bridge task XML file. This portion should be placed inside the task element :Lines between <!- and -- or /* and */ are comments and should not be typed into the editor.

```
<!-- Create a variable named entity Subject -->
<Setup id="entitySubject">
<!-- The first instance. With id instanceHarry -->
<Instance OptionalRequired="0" id="instanceHarry">
<!-- The parameters for this instance -->
<InstanceText>
<script type='loncapa/perl'>
/* The first line must be the instance id */
$entitySubject{instance} = "instanceHarry";
/* The two parameters. Personname = Harry and place=zoo */
$entitySubject{personname} = "Harry";
$entitySubject{place} = "zoo";
</script>
</InstanceText>
</Instance>
<!--End of instanceHarry-->
<!-- The second instance. With id instanceBetty -->
<Instance OptionalRequired="0" id="instanceBetty">
<!-- The parameters for this instance -->
<InstanceText>
<script type='loncapa/perl'>
/* The first line must be the instance id */
$entitySubject{instance} = "instanceBetty";
/* The two parameters. Personname = Betty and place=park */ $entitySubject{personname} =
$entitySubject{place} = "park";
</script>
</InstanceText>
</Instance>
<!--End of instanceBetty-->
```

130

</Setup>

The example above describes a variable question. It has two different possible values for the entity "subject", Harry and zoo or Betty and park. Variables can be placed inside the questions by using the variable name and field name. The first line <Setup id="entitySubject"> creates a variable named entitySubject (based on the id attribute of this line).

The first instance of this variable is shown from lines 2 to 10. Line two <Instance OptionalRequired="0" id="instanceHarry"> marks the beginning of the instance element named instanceHarry (based on the id attribute). The OptionalRequired is given a value of 0. Lines 3-9 determine the actual value of this variable. Lines 3 and 4 must be typed as shown. Lines 5-7 define the instance properties, which must be of the form $< variable_name < (<pre>property_name >) = <value >. The first line of the property must be the instance property (see line 5 of example), with the value being the id of the instance. Other lines (6-7) can be used for any attributes you wish to define. The closing </script>,$

Line 12-21 shows the second instance with the same rules as the first instance. Line 23 </Setup> gives the closing Setup tag which must be as shown. The example of the usage of this variable inside the question is this text:

This is a test question. \$entitySubject{personname} went to the \$entitySubject{place}.

The LON-CAPA engine will replace any instance of \$<variable_name>(<property_name>) with the correct value, depending on the randomly chosen instance.

Based on this code, two different questions are possible:

1. This is a test question. Harry went to the zoo

2. This is a test question. Betty went to the park

17.4.3 .Task Questions and Criteria

The task description should be divided into questions. Questions can also be divided into sub-questions. A question or sub-question must have one or more criteria that are the scoring rubrics used to evaluate that question. A task may also have a criteria. Graders use these criteria to evaluate student work Both questions and criteria are interspersed within the task description, placed where students see them when reviewing their graded bridge task.

Questions are created by using the Question tag. Each question must have a unique id attribute which identifies the question, the value of the id attribute is any text that is unique in the document. Each question must also have the Mandatory attribute which can be set to "Y" if the question is mandatory or "N" otherwise. Finally the question may also have a OptionalRequired attribute, which determines how many optional criteria students must pass to pass the question.

The question element will have the actual text of the question. The questions are created inside the QuestionText element. The question descriptions are placed inside the file by simply typing the text. The text can be marked up to have various formatting. The mark up language used is simple HTML.

Criteria are created using the Criteria tag. The attributes for the criteria tag are similar to the attributes for the questions tag. Criteria tags have id attributes as well as Mandatory attributes. Like for the question tag, the value of the id attribute is any text that is unique in the document, and the Mandatory attribute (values "Y" or "N") determines whether the criteria is mandatory or not. Criteria tags do not have OptionalRequired attributes. The criteria description is created inside the CriteriaText element and can be formatted the same way as the formatting of the questions (using HTML).

The following is an example of a question and criteria element. Question elements are placed inside the task element or inside other question elements. Text between <! - and --> are comments and should not be typed into the editor.

```
<!-- Beginning of question element with id q.testquestion. A mandatory question where the
<Question id='q.testquestion' Mandatory='Y' OptionalRequired='1'>
<!--The text of the question -->
<QuestionText>
Some test explanation
<!--A mandatory criteria with the id of 'criteria.overall.handin'. This criteria will no
<Criteria id='criteria.overall.handin' Mandatory='Y'>
<!--The text of the criteria-->
<CriteriaText>
Criteria text 1
<!--Grader Notes are not shown to the students at all -->
<GraderNote>
This part cannot be seen by students but is used to give additional info to the grader t
</GraderNote>
</CriteriaText>
</Criteria>
<!--End of the criteria -->
<!--An optional question named q.question1 -->
<Question Mandatory='N' id='q.question1' OptionalRequired='0'>
<QuestionText>
The actual test question
<!--A mandatory criteria -->
<Criteria id='criteria.question1' Mandatory='Y'>
<CriteriaText>
Criteria text 2
</CriteriaText>
</Criteria>
</QuestionText>
</Question>
<!--End of question q.question1-->
<!--Some more question text -->
Instructions to the student on submitting files
</QuestionText>
</Question>
<!--End of question q.testquestion-->
   The question that the students will see is:
   "Some test explanation
The actual test question
Instructions to the student on submitting files
```

Any text inside a QuestionText element (lines 2, 14) and not inside a criteria element will be shown to the users. This example has one question, and one optional sub-question. The question element is given in line 1, the id of the question being 'q.testquestion', it is a mandatory question (Mandatory='Y') and it requires that 1 optional question/criteria be passed (OptionalRequired='1'). The sub-question is given in line 13, named 'q.question1', is not mandatory and has no optional questions or criteria that is required to be correctly answered.

The example above shows a code for the creation of criteria. There are 2 criteria in the above question (line 4 and 16). Each criteria has a name (criteria.question1 and criteria.overall.handin) which are both mandatory (the attribute Mandatory is set to 'Y'). The text of the criteria is given inside the CriteriaText element inside each CriteriaElement. The student will never see the criteria when the student is taking the test. The grader will see this on his/her screen:

"Criteria text 1. Grader Note: This part cannot be seen by the students but is used to give additional info to the grader to help evaluating the criteria. Pass Fail

Comment:

Criteria text 2. Pass Fail Comment:

,,

When the bridge task is graded the student will see both the questions and the criteria in his space. Anything inside the GraderNote element (line 7) is not shown to the student. "Some test explanation

Criteria text 1 Pass The actual test question Criteria text 2. Pass Instructions to the student on submitting files "

17.4.4 .Task Finishing Up

Once all questions are written, the file must be closed with the </Task> tag. The file must be saved with a .task extension then placed into a LON CAPA author's folder. To upload the file simply go to the authoring space and simply upload the new file using the upload new document button. Once the file is uploaded to LON CAPA, the author can publish the file so that the domain coordinator will be able to use the file. To do this select publish (or re-publish) in the select action combo box next to the filename.

The LON CAPA interface allows you to view the bridge task from different point of

views. You can see it from the student's view, the grader view, or the student's view after feedback:

- 1. From the list of files authored, click on the bridge task that has just been created/edited. A pull-down menu with the label "Problem Status" is located just above the question
- 2. Select "Answerable" to see the original view, "Criteria Grading" to see a grader view, and "Show Feedback" to see the feedback view .To see the feedback view properly, you must have graded the student with the grader view. Once you have graded using the feedback view however, the answerable view will be similar to the feedback view.
- 3. To reset the view a "Reset Submissions" button is provided.

17.5 Bridge Task Edit Mode

Another way of creating Bridge Task is via the edit mode. The edit mode allows authors to create resources (including Bridge Tasks) online. The basic idea of the this editor is the author inserts and deletes different section types into the file to build the bridge task.

If a task file has already been created, click on the filename followed by the "Edit" button to open the file in the colorful editor.

If a task file needs to be created:

- 1. Enter the filename in the area "Create a new directory or LON-CAPA document" with the combo box at the left of this set to "New File" The filename must have a .task extension.
- 2. At the second screen, press continue to create a new task. At the third screen, select the blank task template and press the "Create task" button to create this blank task.
- 3. To go into the the edit mode, press the "Edit" Button.

The edit mode allows you to insert appropriate sections of a document at certain predetermined places. For example, in a bridge task document, you can insert a question section, a criteria section, and an introductory section. To insert a section, find a drop down box with the label "Insert", and select the section to insert. Then click on the "Submit Changes and Edit" button. The section you selected will be inserted in place of the pull down menu.

Additional insert pull-downs will show up allowing you to insert sections before, inside, and after other sections. The choices on the pull down menu may differ depending on the location of the insert pull-down. For example, the insert pull down inside a question section contains question information; this option is not available anywhere else.

In the edit mode, you will see is an insert button and a optional task button. You will need to enter the number of optional tasks/questions that the student need to answer correctly to pass the bridge task. You can leave this field empty until after you have finished writing the whole bridge task.

This document discusses important sections needed to create a bridge task. These sections can be created in any order.

1. The introductory and closing information 17.5.1

- 2. Variables 17.5.3
- 3. Question and criteria 17.5.2

Once the document has been created, the author must publish the bridge task so it becomes available (See Edit Mode Finishing Up 17.5.4)

17.5.1 Introductions

The introductory information and closing information are just text that are shown to the students but are not part of any questions. The introductory information should be placed at the beginning of the bridge task and the closing information should be placed at the end of the bridge task.

To insert these sections:

- 1. Select "Introductory Information" or "Closing Information" in the insert pull-down menu and press the submit button.
- 2. A new section appears with a text box inside it. You may enter any text inside the text box and the text may be formatted with HTML tags. Everything inside the text box will be shown to the students as introductory or closing text.

17.5.2 Questions and Criteria

The task description should be divided into questions. Questions can also be divided into sub-questions. A question or sub-question must have one or more criteria that are the scoring rubrics used to evaluate that question. A task may also have a criteria. Graders use these criteria to evaluate student work Both questions and criteria are interspersed within the task description, placed where students see them when reviewing their graded bridge task.

Figure 33 shows a screenshot of the question creation page. To create a question:

- 1. Select "Question" in the main insert pull-down (circled as 1).
- 2. Press the submit changes and edit button.
- 3. In this question create a unique id which can be any kind of text (in circle 3).
- 4. Set whether a student must pass this question by setting the value of "Passing is Mandatory" to "yes" (circle 4) or whether this question is optional by setting the value to "no".
- 5. Set the number of optional subquestions/criteria that the students must get correct in order to pass this question. You can also wait until later to fill this in.
- 6. Create the question information by choosing Question information in the insert pulldown (circled as 2) and pressing the submit button.

Figure 33: Bridge Task question creation screenshot

Figure 34: Bridge Task criteria creation screenshot

7. A text box should appear (circle 6) and you can insert any text in this text box. Anything that is typed in this text box will appear to the student as part of the question. HTML tags can also be used to format the text in the text box. Subquestions can be added by inserting a new question (circle 2).

To add a criteria (see Figure 34):

- 1. Instead of choosing "Question" in the insert pull down, select "Question Criteria" (circled as 1). Pressing the submit button will bring up the Question criteria as well as the criteria information where you can write the criteria (Circled 3). The criteria is shown to the student only when the student is reading his/her feedback. The criteria is also shown to the grader in order for the grader to be able to grade the student submission.
- 2. In the criteria block, first create a unique id for this criteria (any text) (circle 1).
- 3. Specify whether a criteria is mandatory or not, this is set in the Passing is mandatory pull-down similar to that of the question (circle 2).
- 4. Text in the text block (circle 4) is shown as the criteria. The text can be formatted with HTML.
- 5. You can also insert a grader note which will only be shown to the user. To do this select "Text to display to grader" in the insert pull down menu of circle number 3.

17.5.3 Parameter and Variable

To create difference versions of Bridge Tasks for each student, parts of the questions are defined using variables. Each variable contains multiple instances of possible values and LON-CAPA randomly selects an instance to give to the student. Figure 35 shows a screenshot of this process.

To create a variable:

- 1. Choose "Setup ..." in the insert pull-down menu (circled 1 in figure).
- 2. Press the Submit Changes and Edit just above the work space.
- 3. A new box should appear with the label "Setup ...". In this box, fill out the id box (circled 3) with any text that is unique to unique to the document. This id is the name of the variable and will be used when creating the values for the variable.
- 4. The setup box has an insert pull-down menu next to the label (circled 2), select "Specific Question Instance" in this pull down menu, then again press the Submit Changes and Edit button.
- 5. This creates one single instance of a set of possible values. For each instance created, a new "Specific Question Instance" must be created.

Required num	<u>ber of passe</u>	<u>d optional ele</u>	ments to pass the	Task: 0

Figure 35: Bridge Task variable creation screenshot

- 6. Right now a box should appear inside the "Setup..." box with the label "Specific Question Instance". Insert a unique id for that instance which can be any unique text (circled 4). This id is the instance name and is used as one of the property of the variable.
- 7. In the question instance block, select "Information for the Instance" in the insert pull down (circled 5). Again press submit button.
- 8. Add a new script (circled 6) in the insert pull down. A new text block should appear.
- 9. In this text box, a perl script will be created (circled 7). A set of parameters for this variable is added. The syntax to set the parameter of a variable is '\$variableName {fieldname} = "fieldValue"'. The variable name is taken from the id field of the Setup block, thefield name is the name of the parameter the author sets, and the fieldValue is simply the value of the field. The first parameter that must be set is the instance field, with the value being an identifier of the instance (which is the id of the specific question instance block).

The example below shows two instances of this script for the variable entitySubject with two instances, 'instanceHarry' and 'instanceBetty'.

The first instance (instanceHarry) is:

```
$entitySubject{instance} = "instanceHarry";
$entitySubject{personname} = "Harry";
$entitySubject{place} = "zoo";
```

The second instance (instanceBetty) is:

```
$entitySubject{instance} = "instanceBetty";
$entitySubject{personname} = "Betty";
$entitySubject{place} = "park";
```

The example above describes a variable question. It has two different possible values for the entity "subject", Harry and zoo or Betty and park. Variables can be placed inside the questions by using the variable name and field name. The example of the usage of this variable inside the question is this text:

This is a test question. $entitySubject{personname} went to the entitySubject{place}.$

The LON-CAPA engine will replace any instance of < variable_name> (< property_name>) with the correct value, depending on the randomly chosen instance.

Based on this code, two different questions are possible:

1. This is a test question. Harry went to the zoo

2. This is a test question. Betty went to the park

17.5.4 Edit Mode Finishing Up

Once the construction is complete, click on the "Submit Changes and View" button. Click on list to list the current author's directory. The author should now publish the file so that the domain coordinator will be able to use the file. To do this select publish (or re-publish) in the select action combo box next to the filename.

The LON CAPA interface allows you to view the bridge task from different point of views. You can see it from the student's view, the grader view, or the student's view after feedback.

- 1. From the list of files authored, click on the bridge task that has just been created/edited.
- 2. A pull-down menu with the label "Problem Status" is located just above the question. select "Answerable" to see the original view, "Criteria Grading" to see a grader view, and "Show Feedback" to see the feedback view.
- 3. To see the feedback view properly, you must have graded the student with the grader view.
- 4. Once you have graded using the feedback view however, the answerable view will be similar to the feedback view. To reset the view a "Reset Submissions" button is provided.

17.6 Setting Up a Bridge Task

The first step in making bridge tasks available to students is to include it in the document space. To do this:

- 1. Enter the course coordinator space for the course
- 2. Go to "Course Documents" and click on import. This page gives the list of files that you have created.
- 3. Select the bridge task and press import to insert the file to the list of documents.
- 4. After importing the document, you must re-initialize the course.

Now the assignment is in the list of documents, but it is not available for students. There are two ways of making bridge tasks available to students. One method is by using slots (the default method), which restrict the bridge task document to open at certain time/place only. The other method allows students to take bridge task like any other Lon-CAPA assignments, that is at any time they want within opening and closing dates. This method does not restrict the access to particular computers or rooms. Any student in the course may open the BT.

If you want to use slots, first create the slots (See Bridge Task and Slots 17.6.1). Once the BT is imported (and slots are created) go back to the document list and click on the bridge task resource, this should take you to a page that shows the resource content. If you are not using slots, click on the bridge task resource. Whether using or not using slots, click on PPRM (a button on the top menu) to modify parameters for this resource. Set the opening date and the due date (if any) in the for resource column. To do this, click on the * in the in course for resource column. A pop up should appear. Enter the date you want the resource to be available and click the store link.

If you are using slots:

- 1. Change the "Use slot based access controls" parameter to "Yes".
- 2. Change the "Slots of availability" parameter for the course in for resource column to the name of the slot that you created. You may need to change the input type (the combo box at the top of the popup) to 'String Value' instead of 'default'.

If you are not using slots:

1. Change the "Use slot based access controls" parameter to "no" by clicking on the \ast in the for resource column

The bridge task should now be available to students. To see the BT in the student view, switch to a student role in your course. Navigate contents and click on the resource.

17.6.1 Bridge Task and Slots

To restrict when and where BTs can be taken, the slots feature of LON-CAPA is used. Slots allow the instructors to specify the room, the time, the students that can take the Bridge Tasks, and finally any proctors that will authenticate the students.

17.6.2 Bridge Task and Conditional Resources

It is possible to configure bridge tasks such that only when a student passes a Bridge Task does the next Bridge Task appear to the student. This feature is useful in such cases as Bridge Tasks are related to one another, and the results of one Bridge Task is needed for the next Bridge Task.

To create configure bridge tasks these way, a sequence page must be created. A resource author starts at his/her authoring space (Main menu: AUTH). Once in the authoring space, the author create a new assembled sequence. See the section 14 for a more concise reference on condition and sequences.

The author must create various conditionals to determine which resources to show. The easiest way to do this is by using advanced edit. The advanced edit visualizes the various conditions and resources. This interface needs popups, so make sure popups are enabled in the browser.

In the main starting view of the advanced edit, there are two squares, marked start and end respectively. Start by creating a link between the start square and the end square. To do this click on the start square (on the row under the text start), select "Link Resource", then click on the end square. A link is now created between the start and the end boxes.

Once a link is created the author adds resources and conditions. Click on the link and then choose insert resource into link. This allows the placement of a resource such as a bridge task into the sequence. Once the resource is placed into the link, the author should create a mapalias. To do this, select the resource, then click on set parameters, and change the value of Custom Parameter to an alias.

Under each square is an area of the same color as the square, these areas can be used to create conditionals to get to the next resource to the sequence. This document only discusses using conditionals to block access to the next resource (including Bridge Tasks).

Add conditionals by clicking on the area just under the squares. A popup window will appear with a condition box and some options. The condition box allows the author to enter a variety of different conditions. To block access to the next resource, select the second option "Blocking this link if false".

The conditions used will be :

```
&EXT('user.resource.resource.0.awarded','<alias of resource>') eq '1'
```

<alias of resource> should be changed to the alias set for the previous resource that the student needs to pass before the next resource is unblocked. If the student has not passed a particular homework/problem/bridge task, the value of user.resource.resource.0.awarded is 0 otherwise the value is 1. This line checks whether the value of user.resource.resource.0.awarded for that resource is equals to 1, if not the link is blocked and the next resources are not shown to the user.

17.7 Handing In Bridge Task Files

After a student finishes creating the Bridge Task, the student must hand in the files. There are many ways to do this, students can email the files necessary, or students can email a link to the instructor that shows where his files are. LON-CAPA provides a way to upload file using the portfolio. The portfolio is a space given to each student which can contain files and is shareable.

The process of handing in files consists of:

- 1. Upload files into portfolio
- 2. Select the files to be submitted
- 3. Submit the files

At the end of every bridge task there will be a box to submit files in the portfolio for grading. When the student click on the link "select portfolio files", a new window is opened showing the content of the student's portfolio. The student can create directories in the portfolio and upload files using the upload file buttons.

Once the files that are needed are uploaded, the student select (by checking the checkbox next to the filenames) of all files that he needs to submit to the instructor. Once all files needed are checked off, the student needs to press the "select checked files and close window" button.

By pressing the close window button, the student's portfolio window should close, and the student should see his or her Bridge Task Page. The text field in the upload files into portfolio should contain the list of names. The student must then press 'submit answer' to submit the answer to be graded. If the student needs to resubmit the file, the student must repeat the process and check off all the files (not only new files) that needs to be submitted. Once a file is submitted, the student may not overwrite or delete the files.

18 WebDAV access to Authoring Space

If your domain has Apache with SSL running on the LON-CAPA server where you access your Authoring Space (i.e., URLs begin https://) and your Domain Coordinator has enabled webDAV access for users with author or co-author roles, then you will be able to connect to an Authoring Space using webDAV.

A webDAV connection allows you to mount the Authoring Space directory tree as an external volume. You can then use your own laptop/desktop computer's file management tools and applications to copy, move, edit and delete files (including dragging and dropping folders, etc.).

The requirement to obsolete published files before moving or deleting them, which applies to the regular web browser-based management of Authoring Space, also applies in the webDAV environment. Moving and deleting directories in the webDAV environment is prohibited if the directory, or any (nested) subdirectory contains a non-obsolete published resource.

Given the ability to easily delete unpublished content in webDAV (without a mechanism to reverse the deletion), it is important that you are especially careful when working in the webDAV environment with this type of content.

When you display the contents of a directory in Authoring Space using webDAV you may see additional files, with extensions .log, .save, .bak etc. for each LON-CAPA .problem file. You can view the contents of these files but you will not be able to modify or delete them. These files are created by LON-CAPA when using the web GUI. For example, a .log file, which records publication history, is updated whenever you use "Publish" to copy a file from Authoring Space to Resource Space, and .bak files enable use of the LON-CAPA "Undo" button in regular web browser-based editing in Authoring Space.

Figure 37: MacOS WebDAV URL

Mac OS 10.9 (Mavericks) and earlier

- 1. Select the "Go" item in the Finder toolbar and select "Connect to Server".
- 2. Enter a URL for a library server where the Authoring Space is located: e.g., https:// < hostname > /webdav/ <dom> / < username >/ where dom is the domain, and username is the username of the Authoring Space owner.
- 3. You will be prompted to enter a username (this will be your LON-CAPA username if you are the author, or your LON-CAPA username, domain if you are a co-author with a domain different to that of the author) and your LON-CAPA password.
- 4. In the directory listing, you can use control + click for a particular file to choose an application to use to open it (e.g., Text Wrangler for .problem files).

Figure 39: MacOS WebDAV Directory Listing

Figure 40: MacOS Editing a file accessed via WebDAV

Figure 41: MacOS 10.10 (Yosemite) ForkLift – Connect to WebDAV

Mac OS 10.10 (Yosemite)

The instructions provided for Mac OS 10.9 and earlier can also be used to mount the Authoring Space if you are using 10.10. However, because of a change in the mechanism used to save files, the Apple webDAV implementation in 10.10 will not allow saving of files in Authoring Space if they have already been published to resource space. However, if you purchase the inexpensive ForkLift 2 utility for Yosemite, you can continue to use the webDAV to modify and save these types of files, when you use ForkLift to set up and manage your webDAV connection.

- 1. Select the "Go" item in the ForkLift toolbar and select "Connect...".
- 2. In the "Connect" dialog select "WebDAV (HTTPS)" as the protocol, and enter the hostname of the server in the Server textbox, and your LON-CAPA username (LON-CAPA username,domain if you are a co-author with a domain different to that of the author), and password Click the "More options" arrow to display the Remote path textbox, and enter webdav/ <dom> / < username >/, where dom is the domain, and username is the username of the Authoring Space owner.
- 3. In the directory listing,

you can use control + click for a particular file to choose an application to use to open it (e.g., Text Wrangler for .problem files).

∞	∞ or ∞	<m>\$\infty\$</m>

20 Appendix: Physical Units

Physical Units Accepted by LON-CAPA

The following subsections show the physical units that LON-CAPA accepts. The symbols must be used when entering the units, for example "35 kg".

Note that compound units are formed by using *, / and $\hat{}$. For example, an acceleration

might be in terms of "m/s²" or meters per second squared. This could also be expressed as "m/s/s". Units of Newton-meters (for torque) would be entered as "N*m". Parentheses may be used to guarantee the correct sense of the unit. Kilometers per Ampere-hour could be written as "km/(A*hr)" or "km/A/hr" but not "km/A*hr". The last option would be interpreted as kilometer times hours per Ampere.

LON-CAPA will automatically perform some conversions between units of the same dimension when units are provided for a problem. You can provide an answer of "1.45 km" for a distance. If the computer expects the answer in cm, it will convert your answer before comparing against the numerical solution.

Please note that if your units are inappropriate, the computer has no way of checking the appropriateness of your answer. If units are required, only once appropriate units are provided will the system check your numerical answer.

Base Units

# name	symbol	comment
meter	m	# length
kilogram	kg	# mass
second	S	# time
ampere	А	<pre># electric current</pre>
kelvin	K	<pre># thermodynamic temperature</pre>
mole	mol	<pre># amount of substance</pre>
candela	cd	<pre># luminous intensity</pre>
decibel	dB	<pre># log of pressure amplitude</pre>

Prefixes

#	Prefix	symbol	factor
yo	tta	Y	10^{24}
ze	tta	Z	10^{21}
ex	a	E	10^{18}
pe	ta	Р	10^{15}
te	ra	Т	10^{12}
gi	ga	G	10^9
me	ga	М	10^6
ki	lo	k	10^3
he	cto	h	10^2
deca		D	10^1
de	ci	d	10^-1
ce	nti	С	10^-2
mi	11i	m	10^-3
mi	cro	u	10^-6

n	10^-9
р	10^{-12}
f	10^{-15}
а	10^{-18}
Z	10^{-21}
У	10^{-24}
	n p f a z y

Derived Units

# Derived Uni	t	
# name	symbol	comment
gram	g	# mass
minute	min	# time
hour	hr	# time
hour	h	# time
day	day	# time
day	days	# time
year	yr	# time
pound	lb	# mass
ounce	οz	# mass
inch	in	# length
foot	ft	# length
mile	mi	# length
yard	yd	# length
nautical_mile	e n_mi	<pre># length, nautical mile (UK)</pre>
rood	rood	# area, rood
acre	acre	# area, acre
hertz	Hz	# frequency
litre	L	# volume
newton	Ν	# force
pound_force	lbf	# force
dyne	dyn	# force
pascal	Pa	# pressure, stress
bar	bar	# pressure
mmHg	mmHg	<pre># pressure, millimeter of mercury</pre>
torr	torr	# pressure
atm	atm	<pre># standard atmosphere</pre>
joule	J	<pre># energy, work, heat</pre>
electronvolt	eV	# energy
calorie	cal	# energy
Btu	Btu	# energy
watt	W	<pre># power, radiant flux</pre>
coulomb	С	# electric charge
volt	V	<pre># electric potential, electromotive force</pre>

ohm	ohm	#	electric resistance, use this in /ANS
ohm	ohms	#	electric resistance
ohm	Ohm	#	electric resistance
ohm	Ohms	#	electric resistance
mho	mho	#	electric conductance
mho	mhos	#	electric conductance
mho	Mho	#	electric conductance
mho	Mhos	#	electric conductance
siemens	S	#	electric conductance
farad	F	#	electric capacitance
tesla	Т	#	magnetic flux density
weber	Wb	#	magnetic flux
henry	Н	#	inductance
radian	rad	#	plane angle
degree	deg	#	plane angle (Pi rad=180 deg)
steradian	sr	#	solid angle
lumen	lm	#	luminous flux
lux	lx	#	illuminance
becquerel	Bq	#	activity (radioactive)
curie	Ci	#	activity (radioactive)
gray	Gy	#	absorbed dose (of radiation)
sievert	Sv	#	<pre>dose equivalent (dose equivalent index)</pre>
astroUnit	AU	#	mean distance earth to sun
celcius	degC	#	multiplicatively OK
fahrenheit degF	# mul	ti	plicatively OK
molarity	М	#	chemisty
amu	amu	#	atomic mass unit
amu	u	#	atomic mass unit
lightspeed	с	#	speed of light
cubiccentimeter	сс	#	cubic centimeter
electroncharge	е	#	elementary charge
hbar	hbar	#	Planck constant
milesperhour	mph	#	miles per hour
rpm	rpm	#	rounds per minute
rpm	rpms	#	rounds per minute
parsec	pc	#	parsec

Interpretation

The coded units are interpreted in the order of basic unit, derived unit, then prefix. For example, "T" will be matched against "tesla" instead of considered the prefix "T". Another example is that "min" will match "minutes" instead of treated as a combination of the prefix "m" and units.
